### COCKER TO DAIS

**COCKER, EDWARD** (1631–1675), reputed English author of a famous *Arithmetic*, the popularity of which gave rise to the phrase “according to Cocker,” meaning “in accordance with strict rule”; i.e., “quite correct.” Cocker was born in 1631. In 1657 he is known to have been living in London, where he worked as an engraver and also taught writing and arithmetic. Samuel Pepys, in his *Diary*, mentions Cocker favourably, and he appears to have been very skilled in his art. He died in 1675, probably in London.

The *Arithmetic* was edited and published in 1678 by John Hawkins, after its reputed author's death, and passed through over 100 editions. Augustus de Morgan in his *Arithmetical Books* (1847) declared that the work was actually written by Hawkins himself, and condemned it as a diffuse compilation from older and better works, but added that “this same Edward Cocker must have had great reputation, since a bad book under his name pushed out the good ones.” Cocker's many other works include several writing manuals, *Cocker's Morals or the Muses spring-garden*, a collection of poems suitable for transcription or translation (1685) and *Cocker's English Dictionary* (1704).

**COCKERELL, CHARLES ROBERT** (1788–1863), British architect and archaeologist, an influential proponent of the classic tradition in 19th-century British architecture, was born in London on April 28, 1788. After training with his father, Samuel Pepys Cockerell (1754–1827), and Sir Robert Smirke (1781–1867), he spent seven years (1810–17) studying and preparing publication on architectural remains in Greece, Asia Minor and Italy. Among his major discoveries were the marbles from Aegina and Phigalia in Greece.

He became a full member of the Royal Academy in 1836, architect to the Bank of England in 1833, and professor of architecture at the academy in 1840. While Cockerell's own architecture occasionally employed a Gothic mode (Lampeter college, chapel at Harrow), he may generally be considered a late adherent of 18th-century neoclassicism, with a more correct antique vocabulary. His principal works were the Ashmolean museum and Taylorian institute, Oxford (1841–45), and the completion of St. George's hall, Liverpool, and the Fitzwilliam museum, Cambridge. He died in London on Sept. 17, 1863. His son, **FREDERICK PEYPS COCKERELL** (1833–78), was also a distinguished architect. (R. RM.)

**COCKERILL, WILLIAM** (1759–1832), English inventor, was born in Lancashire in 1759. He began life by making “roving billies” or flying shuttles. In 1794 he went to Russia, having been recommended to the empress Catherine II as a skilful artisan. For two years he flourished, but on the death of the empress he was flung into prison by her successor. Cockerill escaped to Sweden, and there constructed lock gates for the government; but he could interest no one in his own field of spinning machines. In 1799 he moved to Verviers, Belg., and under contract supplied spinning machines for the firm of Simonis and Biolley. His natural skill as a mechanic was quickly recognized, and in 1807 he was able, with the aid of his two younger sons, to open, in Liège, factories of his own for the construction of spinning and weaving machines. In 1810 an industrial commission acknowledged him as an expert, and he was granted letters of naturalization. He retired from business in 1812, and died at Aix-la-Chapelle (Aachen, Germany), in 1832. (T. M. S.)

**COCKERMOUTH**, a market town and urban district of Cumberland, Eng., 26 mi. S.W. of Carlisle by road. Pop. (1961) 5,827. Area 3.2 sq.mi. It is just outside the Lake District National park and stands at the confluence of the Derwent and Cocker, at a focus of ways among the lower western hills of the Lake district (q.v.). It is the birthplace of the poet William Wordsworth, whose house in the main street was given to the National Trust in 1938. Fletcher Christian, leader of the “Bounty” mutineers, was born at Moorland Close, 1½ mi. S., in 1764.

Settlement in the neighbourhood goes back at least to Roman times, there being a small fort 1 mi. N.W. of the town at Papcastle. Cockermouth was the head of the barony of Allerdale, and Waltheof is said to have built the castle, under the shelter of which the town grew up. There are remains of Norman work in the keep, but the castle is in part modernized as a residence. The town received no royal charter, but the earliest records mention it as a borough. In 1221 William de Fortibus, earl of Albemarle, was granted a market. The Whitsuntide and Martinmas fairs which originated in the 14th century are still held.

Cockermouth forms the agricultural centre of a wide rural area, and there are also within it several light industries, the largest of which produces shoes and slippers.

**COCKFIGHTING**, the sport of pitting gamecocks to fight,

and breeding and training them for the purpose. The game fowl is probably the nearest to the Indian red jungle fowl (*Gallus gallus*), from which all domestic chickens are believed to be descended. The sport was popular in ancient times in India, China, Persia and other eastern countries, and was introduced into Greece in the time of Themistocles (c. 514-449 B.C.). The latter, while moving with his army against the Persians, observed two cocks fighting desperately and, stopping his troops, inspired them by calling their attention to the valour and obstinacy of the feathered warriors. In honour of the ensuing victory of the Greeks, cock-fights were henceforth held annually at Athens, at first in a patriotic and religious spirit, but afterward purely for the love of the sport. On the chair of the high priest of Dionysus, in the theatre at Athens, there is carved a beautiful figure of a winged Eros holding a gamecock just about to fight. Lucian makes Solon speak of quail fighting and cocking, and evidently is referring to an era in Asia, about 3,000 years ago, when cockfighting enthusiasts, lacking the cocks, set quail to fighting quail and partridges to fighting partridges, since both are natural fighters. From Athens the sport spread throughout Greece, Asia Minor and Sicily, the best cocks being bred in Alexandria, Delos, Rhodes and Tanagra. For a long time the Romans affected to despise this "Greek diversion," but ended by adopting it so enthusiastically that Columella (1st century A.D.) complained that its devotees often spent their whole patrimony in betting at the pitside.

From Rome the sport spread northward and was probably introduced into England by the Romans before Caesar's time. Although opposed by the clergy of the Christian church, it nevertheless became popular in the Low Countries, Italy, Germany, Spain and its colonies in the new world and the Philippines, and throughout England and Wales, as well as in Scotland (where it was introduced in 1681). Occasionally the authorities tried to repress it, especially Cromwell, who put a stop to it for a brief period, but the Restoration re-established it among the national pastimes.

From the time of Henry VIII, who added the royal cockpit to his palace of Whitehall, cockfighting was called the "royal diversion," and the Stuarts, particularly James I and Charles II, were among its most enthusiastic devotees, their example being followed by the gentry down to the 19th century. The king's cockmaster presided over the pits at Whitehall. Gervase Markham, in his *Pleasures of Princes* (1614), wrote "Of the Choyce, Ordring, Breeding and Dyeting of the fighting Cocke for Battell," his quaint directions being of the most explicit nature.

Cockfighting mains (matches) usually consisted of fights between an agreed number of pairs of birds, the majority of victories deciding the main; but there were two other varieties that aroused the particular ire of moralists. These were the "battle royal" in which a number of birds were "set" (i.e., placed in the pit at the same time) and allowed to remain until all but one, the victor, were killed or disabled; and the "Welsh main," in which eight pairs were matched, the eight victors being again paired, then four, and finally the last surviving pair.

Among famous London cockpits were those at Westminster, in Drury Lane, Jewin street and Birdcage walk (depicted by Hogarth). The pits were circular in shape with a matted stage about 20 ft. in diameter and surrounded by a barrier to keep the birds from falling off. Upon this barrier the first row of the audience leaned. Hardly a town in the kingdom was without its cockpit, which offered the sporting classes opportunities for betting.

Perhaps the most famous main in England took place at Lincoln in 1830 between the birds of Joseph Gilliver, the most celebrated breeder, or "feeder," of his day, and those of the earl of Derby. The conditions called for seven birds a side, and the stakes were 5,000 guineas the main and 1,000 guineas each match. The main was won by Gilliver by five matches to two. His grandson was also a breeder, and the blood of his cocks ran in the best breeds of Great Britain and the United States. Another famous breeder was a Dr. Bellyse of Audlem, the principal figure in the great mains fought at Chester during race week at the beginning of the 19th century. His favourite breed was the White Pile, and Cheshire Piles were much-fancied birds.

In Wales, as well as in some parts of England, cocking mains took place regularly in churchyards and in many instances even inside the churches themselves. Sundays, wakes and church festivals were favourite occasions for them. The habit of holding mains in schools was common from the 12th to about the middle of the 19th century. When the sport was at its height, the pupils of many schools were made a special allowance for purchasing fighting cocks, and parents were expected to contribute to the expenses of the annual main on Shrove Tuesday, this money being called "cockpence." William Fitzstephen (d. c. 1190) reported that the masters themselves directed the mains, from which they derived a material advantage, as the dead birds fell to them. Cockfighting was prohibited by law in Great Britain in 1849.

Cockfighting was introduced into America at an early date, and it is recorded that George Washington, Thomas Jefferson and Alexander Hamilton were devotees of the sport. Always frowned upon in New England, it was soon forbidden by some of the older states; Massachusetts passed laws against cruelty as early as 1836. The sport is expressly prohibited in Canada and in most states of the U.S. it is specifically forbidden or is repressed by general laws for the prevention of cruelty to animals. Although cockfighting ceased as a public sport in the U.S., Canada and the British Isles, it continued to exist in private in those countries. Portable mains were moved from place to place to avoid police raids, and Sunday morning usually was fight time. In the United States the sport was extremely popular along the Atlantic seaboard and in the south.

Cockfighting is not recognized as a form of sport by the Latin-American countries in general. In Argentina cockfighting was once one of the most popular amusements, but it was suppressed by police measures, although it persisted in several provinces. Paraguay prohibited it by law.

In Cuba, however, cockfighting continued to be a patronized sport regulated by the government. Cubans always supported it and, although it was prohibited for a time, it was reinstated during the Gómez administration (1909-13) and was later regulated by municipal decrees. The sport became popular in Haiti, Mexico and Puerto Rico, an important cockfighting centre. Those who enjoy cockfighting insist that theirs is an amateur—not a professional—sport and that the greatest zest to be obtained from it lies in the many chances to gamble before and throughout a fight. Odds against one bird or the other fluctuate constantly and it is not uncommon for a great deal of money to be wagered. The Club Gallístico, Havana, Cuba, has been the scene of as much as \$100,000 changing hands in a single afternoon. The betting language employed there was especially interesting, being the same as that used in Spain centuries earlier. With the coming of the Castro regime in 1959 the sport was curtailed.

**Breeding and Training.**—Breeders of gamecocks stress pedigree. They regard as fit for championship honours only those birds which have been produced by the blending of strains through hundreds of years, of the world's most courageous cocks. Famous among the strains of the 20th century are the Shawlnecks, Irish Gilders, Eslin Red-Quills, Dominiques, Claibornes, Baltimore Topknots, War-Horses, Irish Grays and Hammond-Gordons.

Gamecocks usually are put to the main when between one and two years of age. Preceding their entrance into the fighting pit, they are given intensive training. As youngsters, they are permitted a great deal of exercise to develop muscles. Chief features of their special diet are cooked corn meal, chopped hard-boiled eggs and occasional helpings of raw beef. This is augmented by regular poultry feed. The birds are massaged with a mixture of alcohol and ammonia, which toughens their skin. Their wings are trimmed at the slope; the hackle and the rump feathers are shortened; the comb is cut as close as possible to reduce it as a target for an enemy bird. In time, the cock is taken to a main, held by a trainer, and brought within a foot or two of another trainee, similarly held. The frenzied efforts of the cocks to get at each other add strength to their muscles. Later the birds get actual fight training by being pitted against each other with heavily padded leather over their spurs.

It is not definitely established when metal spurs first were

slipped over the natural spurs of the gamecocks. The first used were silver spurs, later iron spurs, then steel. In some cockfighting countries—notably Cuba—steel spurs are barred. Instead, bone spurs taken from nonfighting cocks and subjected to a special hardening process are employed. The modern short spur of metal or bone is  $1\frac{1}{2}$  in. or less in length; the longer spur scales from 2 to  $2\frac{1}{2}$  in.

In ancient times cocks were permitted to fight until one or the other was killed. In the more modern era, the rules were amended somewhat. Although some fights still are to an absolute finish, others permit the withdrawal at any time of a badly damaged cock. Other rules fix a time limit for each fight.

On those rare occasions when a gamecock, taking the worst of it, decides he does not wish to continue battle, he makes his intent known by lifting his hackle. The underpart of the hackle is edged with white feathers, and from this act is derived the expression "showing the white feather," which means cowardice. When a cock refuses to fight longer, his handler puts him breast to breast with the other bird. If he still refuses, it is ruled that he has quit and the fight ends.

At all mains, the judge is in supreme control. His word is absolute law, even as to the gambling, and it is binding on all those identified, either officially or unofficially, with a cockfight. There is no appeal from his decisions in anything relating to the main.

See A. Rupert, *Art of Cockfighting* (1949); G. R. Scott, *History of Cockfighting* (1957).

**COCKLE**, the common name applied to any species of marine clam belonging to family Cardiidae, also known as heart clams. The latter name describes the shape of the cross section of the opposed valves and is derived from the Greek *kardia*, "heart." The family, a large and important one, is world-wide in distribution and includes about 53 genera and subgenera and perhaps 250 recent species. They range in size from less than one-half inch in diameter to the smooth giant cockle, *Laevicardium elatum*, from California, which may reach nine inches. The shells are equivalve and the sculpture and colour patterns are variable. Many species lack pronounced sculpture while others are ornamented with radial ribs that are often covered with scalelike processes; among the latter kinds is the common cockle, *Trachycardium muricatum*, found from North Carolina to South America. Some species are of a uniform colour, others have radiating bands of colour and in some the pattern is mottled. The colours are usually browns, reds and yellows.

A few species live in the intertidal zone although most live just below the low-tide line and a few, mostly small species, have been dredged from depths of more than 300 fathoms. All species are found in sandy or muddy areas buried to a depth of not more than one inch. Most members of this family probably have a rather extended breeding season. To judge from the work done in the British Isles and Japan, it may extend over a period of five to six months. The eggs and sperm are shed into the sea, where fertilization takes place, and the young larvae are free-swimming for a considerable period before settling to the bottom.

*Cerastoderma edule*, the best known of the cockles, is an important food in the British Isles and western Europe. Like all other cockles, they are active clams with a large muscular foot and short siphons. They are usually found buried just below the surface of the sand, with the siphons extending to the surface for feeding and respiration. (See **BIVALVE**.) They burrow actively, can crawl short distances on the surface and can re-bury themselves when disturbed. Colonies in unprotected areas are often destroyed by storms and consequently the large fisheries are either in protected bays or estuaries, often in areas where there is some admixture of fresh water. The clams are gathered by hand or by using a variety of rakes or scrapers. In some areas the fishermen bring the cockles to the surface by treading. More than 300,000 cwt. are gathered in England and Wales each year. The average marketable cockle is about one inch long and about two to three years old. In preparing the clams for market they are first boiled to loosen the bodies, which are then separated from the shells by sieving. The meats are washed thoroughly and are then sent directly to market or are preserved in salt or vinegar. They are

BY COURTESY OF MUSEUM OF COMPARATIVE ZOOLOGY, HARVARD COLLEGE  
OPPOSING VALVES OF COMMON COCKLE OR HEART CLAM (TRACHYCARDIUM MURICATUM)

also often eaten raw, though they are not sent to market in this condition. Considerable numbers are canned and these are usually used as hors d'oeuvres.

In most other areas of the world cockles are not found in sufficient numbers to make them commercially valuable. They are eaten, however, wherever they occur. The large basket cockle, *Clinocardium nuttalli*, is fished in Puget sound, Wash.; in Japan the torgai, *Papyridea (Fulvia) mutica*, is one of the

most widely used of the edible clams. In Australia clams belonging to the family Glycymeridae are referred to commonly as dog cockles; they are called cockles probably because the shell superficially resembles that of the true cockle, of which there are about 12 species in Australia. The Sydney cockle is a common name applied to *Anadara trapezia*, a species of Arcidae. These clams were an important source of food to the Australian aborigines.

Cockles are also important as a source of food for birds and a variety of bottom-feeding fishes. The ravages of these predators on the commercial beds of *C. edule*, when combined with those of predatory snails and starfish, often become of real concern to the British fishermen.

Cockles are among the most beautiful of the bivalves. They were used by primitive peoples for decoration and utensils and today are sought by shell collectors. The smaller species are used in making shell jewelry.

Cahn, *Clam Culture in Japan*, General Headquarters Supreme Commander for the Allied Powers, Natural Resources Section Report no. 146 (1951); W. J. Clench and L. C. Smith, "The Family Cardiidae in the Western Atlantic," *Johnsonia* 1, 13:1-32 (1944); Joyce Allan, *Australian Shells* (1950); J. E. Fitch, "Common Marine Bivalves of California," *Calif. Fish Game Bulletin* no. 90 (1953). (R. D. T.)

**COCKLEBUR**, any weedy plant of the genus *Xanthium*, of the family Compositae (q.v.), called also clotbur and burweed. They are coarse, rough, sometimes spiny annual herbs with much-branched stems, one to six feet high, and mostly long-stalked, variously lobed leaves. The male and female flowers, both small and inconspicuous, are borne on the same plant. The fruit (achene) is enclosed in pairs in an oblong bur, about an inch in length, covered with hooked spines and ending in a one- or two-toothed beak. The ripe burs adhere to the hair of animals, which widely disseminate the plant.

JOHN H. GERARD  
COCKLEBUR (XANTHIUM)

When abundant, cockleburs are injurious to crops, but they may be controlled by intensive cultivation, mowing or spraying with 2,4-D, preferably in bright sunshine when air temperature is 70° F. or above.

The germinating seeds and young plants, while in the seed leaf stage, contain a toxic glucoside and cause fatal poisoning when eaten by livestock. The crude drug stramonium (from *Datura* species) is often adulterated with the leaves of *X. strumarium*.

(N. Tr.)

**COCKNEY**, a colloquial name applied to Londoners generally but more properly confined to those born within the sound of the bells of St. Mary-le-Bow church. The origin of the word has been the subject of many guesses, but the historical examination of the various uses of "cockney" by Sir James Murray (see

Academy, May 10, 1890, and the *New English Dictionary*, s.v.) shows that the earliest form of the word is *cokenay* or *cokeney*; i.e., the *ey* or egg, and *coken*, genitive plural of "cock," "cocks' eggs" being the name given to the small and malformed eggs sometimes laid by young hens (cf. Langland, *Piers Plowman*, A, vii, 272).

The word then applied to a child overlong nursed by its mother, hence to a simpleton, and Chaucer, *Reeve's Tale*, used it with *daf*; i.e., a fool. The application of the term by country folk to town-bred people, with their ignorance of country ways, is easy. Thus Robert Whittington or Whittington (fl. 1520) speaks of the "cokneys" in such "great cytees as London, York, Perusy" (Perugia). It was not till the beginning of the 17th century that "cockney" appears to have been confined to the inhabitants of London.

The so-called cockney accent was chiefly characterized in the first part of the 19th century by the substitution of a *v* for a *w*, or vice versa. The chief consonantal variation which now exists is perhaps the change of *th* to *f* or *v*, as in "fing" for thing, or "farver" for farther. This and the vowel sound change from *ou* to *ah*, as in "abaht" for "about," were illustrated in the "coster" songs of Albert Chevalier. The most marked change of vowel sound is that of *ei* for *ai*, so that "daily" becomes "dyly." Contrary to popular belief, the omission of *h* is not peculiar to cockney.

**COCKROACH**, the name applied to members of the Blattidae, a family (sometimes considered an order, Blattaria) of orthopterous insects, with flattened bodies, long, threadlike antennae and shining leathery integument. The name is a corruption of the Spanish *cucaracha*; in the U.S. it is commonly shortened to "roach."

They are chiefly tropical, but certain species have become widely disseminated through commerce and are now cosmopolitan. Cockroaches are nocturnal in habit, hiding themselves during the day. The domestic species are omnivorous but are especially addicted to starchy or sweetened matter of various kinds; they also attack food, paper, clothing, books, shoes, bones, etc., and dead insects. As a rule cockroaches damage and soil far more than they consume, and many species emit a disagreeable odour.

The oriental cockroach (*Blatta orientalis*), a cosmopolitan household pest, is dark brown; males are short-winged, females vestigial-winged. The larger, fully winged American cockroach

JOHN H. GERARD

ORIENTAL COCKROACH (BLATTA ORIENTALIS)

(*Periplaneta americana*) infests buildings throughout the tropics and warm-temperate zones. The German cockroach (*Blattella germanica*), small and pale with two dark lines on the pronotum, occurs with man from the tropics to high latitudes. Eggs of most cockroaches are laid in cases (oothecae) which are carried protruding from the female's body until hidden in some crevice. Oothecae of *P. americana* contain 10 to 16 eggs, which hatch in 40–45 days; nymphal life is 11–14 months, adult life 3–12 months. *B. orientalis* lives about one year.

Of the about 1,600 species of cockroaches known, only 62 species, many introduced, occur in North America; Great Britain has only 2 native species. Although blattids are usually drably coloured, some tropical species are elegant in form and beautiful in coloration. Some species are giants with a wingspread of more than five inches. Although these insects are usually viewed with disgust, they are not devoid of interest. They are the most primitive of living winged insects, and are among the oldest fossil

insects. Their generalized structure and large size make them convenient for study and dissection, and they are widely used as the most suitable type for commencing the scientific study of insect morphology.

Insecticides used for cockroach control, most of which are poisonous to animals and man, include chlordane, one of the most effective; DDT; pyrethrum; and sodium fluoride, which was used for many years.

See also ORTHOPTERA.

Lucas, *British Orthoptera* (1920); Morgan Hebard, *Blattidae of North America* (1917); Phil Rau, "Life History of the American Cockroach," *Ent. News*, vol. li (1940); E. A. Back, *Cockroaches and Their Control*, U.S. Department of Agriculture Leaflet 144 (1937). (T. H. HL.)

**COCKSCOMB**, cultivated forms of *Celosia argentea cristata* (family Amaranthaceae), in which the inflorescence is monstrous. In some there is a flat "fasciated" axis bearing numerous small chaffy, brilliantly coloured flowers while in others the cluster may be spirelike, or fan-shaped. The plant is a low-growing herbaceous annual, a native of Asia, easily grown in the garden, but tender to frost. In cool regions seed should be sown in the greenhouse six to eight weeks before outdoor transplanting is safe. They do best in regions with plenty of summer heat and reasonable moisture. Seed can be sown directly outdoors in warm regions. (See AMARANTH.)

*Celosia floribunda*, a related plant, is cultivated in California under the name cockscomb, but is shrubby. (N. TR.)

**COCLÉ**, a small province (area 1,944 sq.mi.) in southern Panama, facing the Gulf of Panama. Its eastern border is less than 50 mi. from the Panama Canal Zone, with which the province is connected by modern highways and frequent boat service. Population in 1960 was 93,156, of which over 80% was rural. The province has some of the best agricultural lands of Panama and produces sugar, coffee, rice, corn and a variety of fruits and vegetables and animal products, large quantities of which are shipped to urban centres in and near the Canal Zone.

The provincial capital of Coclé is Penonomé (pop. [1960] 4,266). (C. F. J.)

**COCO** (also called the SEGOVIA, WANKS or YARE), Central American river with headwaters in the departments of Nueva Segovia and Estelí, Nicaragua, and Choluteca, Honduras. From the continental divide, which lies within 50 mi. of the Pacific, the river flows northeastward over 300 mi. to the Caribbean which it reaches at the cape and town of Cabo Gracias a Dios, Nicaragua.

Canoes navigate between the mouth of the Júcaro and Bocay rivers, tributaries of the Coco. Larger craft operate between Sansang and the coast in the wet season. (J. T.)

**COCOA** (CACAO), the tropical tree from which cocoa powder and chocolate are derived. Cocoa trees are of the family Sterculiaceae, generally *Theobroma cacao*, rarely *T. pentagona* or *T. sphaerocarpa*; they are not to be confused with the coconut palm (*Cocos nucifera*) or with the South American coca shrub (*Erythroxylon coca*), the leaves of which contain a stimulant, cocaine.

The cocoa tree, a native of Central and South America, may attain a height of 40 ft. in a natural condition; however, in cultivation it is generally pruned to 15–25 ft. for ease in harvesting the fruit. It has a wide-branching habit; the downy surfaced twigs support drooping leathery leaves, often a foot long. Small pinkish blossoms, borne directly on the tree trunk and on larger branches, are followed by green, podlike fruits, which when ripe range in colour from yellow-orange to dark reddish-purple. The mature pods, resembling enlarged cantaloupes or cucumbers (6–14 in. long and 2–5 in. in diameter), are five-ribbed and woody; within, 25–50 almond-shaped, whitish, lavender or purplish seeds (approximately 1 in. across) are imbedded in a white or pinkish, mucilaginous pulp.

The fact that these seeds provide materials useful as food and drink was well known to the pre-Columbian natives of its source area, tropical Middle America, particularly to the Mayas and Aztecs who used the beans also as a medium of exchange. The Aztecs

used cocoa as a beverage, the ground roasted seeds being whipped up in hot water and flavoured with vanilla and spices. On his fourth voyage in 1502, Columbus took back cocoa beans to Spain, where the drink was greatly improved by the addition of sugar. For nearly 100 years the Spaniards kept their secret, but the use of cocoa spread slowly to other parts of Europe. In 1657 a Frenchman opened a shop in London, at which solid chocolate for making the beverage could be purchased at 10s. to 15s. a pound. At this price only the wealthy could afford to drink it, and there appeared in London, Amsterdam and other European capitals fashionable chocolate houses, some of which later developed into famous clubs. About 1700 the English improved chocolate by the addition of milk. The reduction of the cost of the beverage was hampered in Great Britain by the imposition of high import duties on the raw cocoa bean, and it was not until 1853, when the duty was lowered to a uniform rate of 1d. a pound, that chocolate became popular.

Chocolate manufacture started in the American colonies in 1765 at Dorchester, Mass., using beans brought in by New England sea captains from their voyages to the West Indies. James Baker financed the first mill, which was operated by an Irish immigrant, John Hanan. Water power was used for grinding the beans.

The ground cocoa bean, prior to further processing, is 50% or more natural vegetable fat, called cocoa butter; in the manufacture of cocoa powder part of the fat is removed and in the manufacture of chocolate, cocoa butter is added. The development of both products therefore depended upon a method of extracting fat from the ground beans. The use of presses for this purpose was mentioned in books as early as 1753, but it was not until 1828 that Conrad J. van Houten took out a patent on the use of presses in the production of cocoa powder. This made available cocoa butter as a by-product, and when sufficient quantities became commercially available the manufacture of sweet eating chocolate became practical. This eating chocolate became popular around the middle of the 19th century and coating chocolate for use on candies and biscuits (cookies) came into use soon afterward. Milk chocolate was introduced in Switzerland in 1876 by M. D. Peter and its popularity spread throughout the world.

**Cocoa Production.**—Centres of production have changed with time, but commercial cultivation is limited by natural factors to the tropics; practically all development is within 20° north and south of the equator, and the main African belt is less than 10° from the equator. High temperatures, a mean shade temperature of approximately 80° F. with diurnal and seasonal variation of not more than 15° F., appear necessary. The cold limit apparently is an absolute one, whereas temperatures of 100° F. or more, accompanied by high humidity, do no harm.

Well-distributed rainfall of at least 50 in. a year (if not irrigated), absence of disease, a considerable population to provide harvest labour and access to export markets are all factors favouring development. In South America there are large areas apparently suitable for cultivation except for disease. Favourable site factors include a well-drained, porous soil of considerable depth and rich in humus, an altitude of a few hundred feet, protection from strong winds and some shade.

Centres of production, judged by exports, soon shifted from Mexico to Venezuela; Ecuador was the principal area from about 1850 to 1910, after which Brazil led for a time, only to be surpassed by the rapidly developing west African cocoa belt, which was the leader after 1920 and by mid-century was producing approximately two-thirds of the expanded world crop of about 2,000,000,000 lb. annually. Production in the Americas has continued at an annual rate of nearly 200,000 tons over many years.

In the 1950s a trend toward incipient decline appeared in the major centres of production, especially those of Africa. The spread of plant disease was a partial explanation, though chemical sprays appeared to offer a solution to at least some disease problems. Many major plantings were passing beyond the most productive age period; new plantings apparently did not keep up with the loss of trees, partly because of economic competition with other production. Price uncertainties were a factor. Plantings in some new or minor areas were expanding, but the high cost of establishing plantations and bringing them to producing age

made such ventures somewhat speculative.

**The Cocoa Farm.**—Most of the world's cocoa production comes from the modest two to five acres of small farmers. Probably not more than 10% of the African production of base-grade cocoa—but more of the American production of flavour grades—is from larger plantations under co-operative native groups or non-native management.

**Cultivation.**—Preparation of the area for planting consists mostly in slashing and burning existing vegetation, perhaps girdling tall trees and leaving others for shade. Planting, except under more advanced management, is by rather closely spaced seeding, sometimes later thinned to keep the stronger plants. In other cases, nursery-grown and selected seedlings are transplanted when about two feet high, with field spacing ten feet or more apart. There is some tendency to abandon the use of seedlings in favour of more certain vegetative propagation of superior strains by cuttings and bud grafting. Shade by food plants, especially bananas, is provided in most areas for the thinner plantings. The tree, which would grow eventually to 30 to 40 ft. in height, is generally pruned to 15 to 25 ft. to aid harvesting. There is little cultivation or fertilization other than slashing undergrowth. The tree begins to bloom and fruit three or four years after planting and reaches full production about the eighth year. There is disagreement as to the length of fruiting life, but 30 to 40 years is common and nearly 100 years is reported. There is some evidence that from the standpoint of production and disease control it is desirable to replace trees after 15 to 30 years.

Cocoa trees are victims of a number of plant diseases. The most widespread is a fungus disease known as black pod, caused by *Phytophthora*, which in many cases destroys up to 40% of the potential crop. It can be controlled by spraying with Bordeaux mixture. A second fungus known as witches'-broom, caused by *Marasmius perniciosus*, is prevalent in Trinidad, Ecuador and eastern Venezuela. *Monileia* pod rot is found in Ecuador. A virus disease, swollen shoot, has caused great damage in west Africa, the best remedy being to cut out and burn affected trees. Many insects also cause direct damage to the trees.

**Harvesting and Treatment.**—A full-grown tree produces annually approximately 6,000 small pink blossoms directly on the trunk and main branches, of which from 20 to 40 mature into fruit pods. Though these ripen intermittently throughout the year, most ripen in one or two main periods. Four-fifths of the world crop is harvested in the period from September to March. The pod is simply cut from the tree and the tough, fibrous hull opened with a machete, after which the seeds and adhering pulp are scooped out and fermented. The fermenting, whether carried out in a primitive pile on the ground or in a more modern perforated box or tank under cover and high temperature, takes 3 to 10 days, depending on the type of cocoa, and involves draining away the juicy "sweatings" of the pulp and the mixing and stirring of the beans to obtain an even fermentation and to avoid under- or over-fermentation. The germ in the seed is killed by the heat, temperatures as high as 124° F. develop, and at this time are formed the precursors responsible for chocolate flavour when the beans are roasted. The beans become plump and full of moisture; the interior develops an even, reddish-brown tint and a heavy, sharp fragrance. The pulp is easily removed. The beans are then dried, in some cases after washing. Drying is sometimes done on special mats or racks, and it may be by sun or artificially; it takes a few days or weeks, until the water content is reduced to 6% to 8%. The beans may then be bagged in burlap for handling. Unwashed, sun-dried beans seem to be preferred; unfermented beans are not desired. The yield on the average is 1 to 2 lb. of cured beans per tree per year, or about 350 lb. per acre. Selected plantings with above-average care will yield much more. There is some evidence of higher yields in alternate years. A major problem, other than that of disease, is how to combine peasant production with more advanced techniques to get higher yields and better quality, preferably at lower cost. Typical costs are extremely difficult to estimate, but west Africa, with its small farmers depending largely on family labour, is the lowest-cost producing area.

**Grades and Marketing.**—Cocoa is classified in world trade

as base or flavour grades, or as ordinary and fine. In general, these grades relate not to difference in processing but to varieties, of which there are many, the two main groups being Criollo and Forastero. Approximately 10% of world production is of the fine or flavour grades called Criollos, Trinitarios or high Forastero, marketed especially under the trade names of Arriba, Maracaibo, Caracas and Trinidad Estates and produced mostly in Venezuela, Ecuador, The West Indies, Ceylon and Java. They are largely grown under a plantation system utilizing 100 ac. or more. Forastero types constitute the base or common grades, marketed as Accra from Ghana (where they constitute half the export trade and the main source of income for the majority of the people) and Bahia from Brazil, as well as Lagos from Nigeria and Sanchez from the Dominican Republic. They usually constitute about 90% of the world's crop, are hardier and give larger yields of medium-quality beans selling for lower prices than the flavour grades. Quality standards for cocoa deteriorated during and after World War II, not only because of increased use of ordinary grades, flavour grades being available in comparatively small amounts, but also because of relaxed standards under wartime conditions. However, governments intervened in an effort to improve grading and to provide premiums for quality.

The annual crop of cocoa moves into world commerce promptly, partly because local use is not large. Though the beans will keep for a year or more under the best of storage conditions, two or three months is about the limit under the tropical conditions prevailing in the producing areas. The major markets are western Europe and the United States. Four-fifths of the exports go to five countries, and ten countries take 95% of the beans entering world trade. Cocoa was bought and sold before World War II essentially on a free but unstable market, involving active middlemen and comparatively wide price fluctuations. Growers of cocoa had no experience with international regulatory agreements; most of the proposals at prewar conferences were in the direction of increasing consumption by advertising and keeping prices as low as possible. There were tight controls over trade during the war: the same price was paid for all west African cocoas during 1942-46, whereas except during periods of short supply the best grade sold for about three times as much as the lowest. Stocks were much reduced at the end of World War II, and production had declined fully one-fifth, not because of war devastation of the producing areas but largely because of a general disruption of the production pattern and as a result of disease. In the early postwar years, world cocoa trade was governed in a general way by the International Emergency Food council. Allocations ended in 1949. Though world production staged some recovery after 1948, particularly in Latin America and French African territories, the major African areas continued below prewar production. Supplies available to the more important consuming countries were about 10% less per capita than prewar. Demand associated largely with recovery in Europe and the Korean outbreak inflated prices to new record levels. Spot Accra sold at a record price of 72.9 cents per pound in 1954. Though the search for acceptable synthetic or other substitutes appeared generally unsuccessful, chocolate bar goods were lightened and coatings thinned.

**Manufacture and Uses.**—The United States has the world's largest industry, ordinarily taking as much as 30% of the world's exports and reducing the raw cocoa beans to the several products. There are also major cocoa-manufacturing centres in several western European countries and in Canada, Australia and India.

**Processing Cocoa Beans.**—After being cleaned and sometimes washed, the beans are carefully roasted at 275° to 350° F. to develop flavour, colour and aroma and to aid shelling; they are then broken into particles called nibs by a rolling or cracking process, and winnowed to remove the fibrous shells. The shells, 10%-14% of the total weight, may be used for cocoa "tea" but usually are used in fertilizers. The nibs of desired grades and flavours are blended and ground to a cocoa mass or chocolate liquor, which after cooling sets into a hard brown block. Part of the natural fat—cocoa butter—may then be removed by hydraulic pressure. Various types of chocolate may result, depending on the amount of butter remaining, flavouring added and further processing.

Unsweetened chocolate or baking chocolate is the ground nib molded into bars. Sweet drinking chocolate has had sugar added and has been somewhat refined. Eating chocolate contains more cocoa butter and flavouring.

**Sweet Chocolate.**—In the manufacture of sweet chocolate, granulated or pulverized sugar is mixed with the chocolate liquor and the resulting paste is ground by passing it over steel roll refiners. As the addition of sugar reduces the over-all fat content, additional cocoa butter must be supplied to the mix to maintain sufficient fat to permit further processing and molding. A typical sweet chocolate contains 42% chocolate liquor, 42% sugar and 16% added cocoa butter. After the processing, the sweet chocolate is cooled and molded into cakes for use by the candy industry as a coating for centres or it may be cast directly into small bars suitable for eating.

**Milk Chocolate.**—Milk chocolate is sweet chocolate in which the flavour has been modified by the addition of whole milk solids. The U.S. standard calls for a minimum of 12% whole milk solids, but good quality chocolates may contain as much as 20% to 22%.

**Cocoa Powder.**—Part of the fat or cocoa butter has been removed from cocoa powder, but it contains from 10% to 22% or more fat and is sometimes treated with an alkali salt which neutralizes the natural acidity of the cocoa and deepens the colour.

**Cocoa Butter.**—The pure fat extracted by pressure from the ground and crushed cocoa bean is used in the manufacture of confectionery and in toilet preparations. Cocoa butter is also sold free from combination with other drugs for treating skin irritations where a pure fat is necessary.

Chocolate and cocoa are used in several ways in the confectionery, baking, dairy and soft drinks and ice cream industries. Of all candy flavours, chocolate is generally the most popular. In addition to the mild stimulating effect caused by theobromine (2.2%) and caffeine (0.1%), cocoa is a concentrated food containing about 40.3% carbohydrates, 22% fat, 18.1% protein and 6.3% ash, with small amounts of water and fibre; it provides approximately 2,214 cal. per pound. See also CONFECTIONERY MANUFACTURE.

Wickizer, *Coffee, Tea and Cocoa: an Economic and Political Analysis* (1951). (J. K. R.; N. W. K.)

**COCO DE MER (DOUBLE COCONUT)**, a palm, *Lodoicea maldivica*, native of the Seychelles Islands. The flowers are borne in enormous fleshy spadices, the male and female on distinct plants. The fruits, among the largest known, take ten years to ripen; they have a fleshy and fibrous envelope surrounding a hard, nutlike portion that is generally two-lobed, suggesting a double coconut. The contents of the nut are edible. The empty fruits (after germination of the seed) are found floating in the Indian ocean, and were known long before the palm was discovered.

**COCONUCO**, a group of South American Indians in south highland Colombia whose language was probably a branch of the Macro-Chibchan phylum (see CHIBCHAN). Assimilated by the Spaniards soon after the conquest, their culture is known only from scant historical references. The Coconuco, together with the Mogueux, comprised a dozen or more tribes which resembled their Andean neighbours in carrying on intensive agriculture and having a dense and settled population, federated states and developed warfare. Unlike their neighbours, the Coconuco proper were not cannibals.

See Henri Lehmann, "The Mogueux-Coconuco" in *Handbook of South American Indians*, ed. by Julian H. Steward, Bureau of American Ethnology bulletin 143, vol. 2, pp. 969-974 (1946). (J. H. St.)

**COCONUT OIL AND CAKE:** see COPRA.

**COCONUT PALM** (*Cocos nucifera*), best known of the palms and famed as one of the world's most important crop trees. Its slender, leaning, ringed trunk arises (often 100 ft.) from a swollen base, and is surmounted by a graceful crown of giant, featherlike leaves. About a dozen new leaves appear periodically

each year, and an equal number of compound flower stalks, protected by woody spathes, push out from the base of the older leaves. About 10,000 male flowers and about 30 female flowers appear on each stalk. They mature at different times, assuring cross-pollination. Flowering begins in trees five years old and is continuous thereafter. Fruits require a year to ripen; the annual yield per tree may reach 100, but 50 is considered good.

Mature fruits—ovoid or ellipsoidal in shape, 12 to 18 in. in length and 6 to 8 in. in diameter—have a thick fibrous husk surrounding the familiar single-seeded nut of commerce. A hard shell encloses the insignificant embryo with its abundant endosperm, comprised of both meat and liquid. The three "eyes" of the coconut shell indicate that three ovarian cavities exist in the flower, but only one persists at maturity.

Coconut fruits float readily and have been dispersed widely by ocean currents, and also by man, throughout the tropics. Actually the native home of the coconut palm is unknown, but it probably originated somewhere in Indo-Malaya, where the palm exists in many natural forms. Marco Polo was among the first Europeans to describe coconuts, but the great voyages of discovery such as that of the navigator William Dampier made the species better known. Coconut palms flourish best close to the sea on low-lying areas a few feet above high water where there is circulating ground water and an ample rainfall. The palm sometimes is grown far inland and at altitudes up to 2,000 ft., but in such places production declines. Most of the world's coconuts are produced on small native plantations. Propagation is by the unhusked ripe nuts. These are laid on their sides close together in nursery beds and almost covered with soil. After four to ten months the seedlings are transplanted to the field where they are spaced at distances of 25 to 30 ft. Various annual crops are often interplanted in young plantations until the palms start bearing, usually after five to six years. Full bearing is obtained in 15 years. Yields continue to be profitable until trees are about 50 years old.

Like most cultivated plants, the coconut palm is subject to many pests and diseases. Particularly serious are the rhinoceros beetle, the red coconut weevil and a bud rot disease—all of which destroy many palms by fatally injuring the tender terminal bud.

The coconut attains its greatest marketable value as copra (*q.v.*), the dried extracted kernel, or meat, from which coconut oil, the world's ranking vegetable oil, is expressed. It is estimated that 1,000 mature nuts will yield more than 500 lb. of copra, from which 25 gal. of oil may be obtained. The oil is a white solid substance at ordinary temperatures with a peculiar, rather disagreeable odour. The Philippines and Indonesia lead in copra production, and throughout the southeast Pacific area copra is one of the most important export products. In the early 1960s approximately 400,000 metric tons of coconut oil entered world trade annually. The principal importer and consumer is the U.S., which imports both copra and crude coconut oil in large quantities. Western Europe—particularly west Germany, the Netherlands, France and the U.K.—is important also as a consumer of copra and coconut oil. Coconut oil has many uses, entering into the manufacture of soaps and shampoos, detergents, edible oils, margarines, vegetable shortenings, synthetic rubber, glycerin, hydraulic brake fluid and plasticizers for safety glass. Copra meal is a livestock feed and fertilizer, and shredded coconut is a familiar item on grocers' shelves.

Although the coconut finds its greatest commercial utilization in the industrial countries of the western world, its usefulness in its native areas of culture is even greater. Indonesians claim that coconuts have as many uses as there are days in the year, and these are not limited to the oil-yielding nut. Besides the edible kernels and the refreshing and palatable drink obtained from green nuts, the husk yields coir, a fibre highly resistant to salt water and used in the manufacture of ropes, mats, baskets, brushes and brooms. Coir is a by-product of copra production obtained by retting the husks in water and then separating out the fibres by hand or machinery. The best coir comes from green husks. Three types of fibre are produced—mat fibre, bristle fibre and curled fibre. Coir dust, or coco peat, is a peat substitute of use to horticulture.

When wounded or cut, the young inflorescent stalks produce a

sweetish sap which yields toddy, a beverage drunk fresh, fermented or distilled; toddy is a source of sugar as well as alcohol. As with other palms, the delicate young bud cut from the top of the tree is eaten as a salad vegetable, palm cabbage; the mature leaves find use in thatching and basketry; and the fibrous decay-resistant trunk is of value not only to the islanders, who incorporate it into the construction of huts, but also as an exported cabinet wood, porcupine wood.

See also PALM; and the references under "Coconut Palm" in the Index. (WR. H. H.)

**COCOPA**, a Yuman (*q.v.*) tribe at the delta of the Colorado river in Mexico. The 3,000 Cocopa in the period of Spanish contact dwindled to about 600 by 1942, half of whom were in the United States. Cocopa customs closely resembled those of the Mohave (*q.v.*) and Yuma but diverged in social and religious life. Agriculture provided a third of their subsistence as against a half among the Mohave, and their warlike proclivity was less. Modifications of social and ceremonial life were in the direction of southern California tribes. Women were known by clan names but also bore personal names. Dreams of supernaturals, rather than of myth episodes, gave special abilities, with the administration of jimson weed to induce dreaming. An initiation to manhood was held at puberty. At a six-day commemorative ceremony dancers impersonated the dead, and a building dedicated to the dead was burned with offerings.

See E. W. Gifford, *The Cocopa*, University of California Publications in American Archaeology and Ethnology, vol. 31, no. 5 (1933). (L. SP.)

**COCOS (KEELING) ISLANDS**, two atolls forming an isolated Australian territory in the Indian ocean, lie about 840 mi. S. of the equator and about 2,300 mi. W. of Darwin, Austr. Pop. (1964) 684. Land area about 5 sq.mi. The southern atoll, which is the main one, supports about 24 linear islets, of which Home, Direction and West Island are inhabited; about 16 mi. N. is the lesser atoll, from which rises only the uninhabited North Keeling Island.

The main atoll is about 10 mi. across at its widest point, and at the north end has an entrance to the shallow lagoon. Periodical earthquakes are experienced. The climate is healthful and equable with a temperature range of 70°–89° F.; the southeast trade wind blows for most of the year but in the early months damaging cyclones may occur. Except for imported plants and grasses the main growth is coconut palms. There are no indigenous mammals; sea birds abound and turtles live in the lagoon. The giant robber crab *Birgus latro* subsists on fallen coconuts.

Discovered in 1609 by the British mariner William Keeling, the islands were first settled in 1823 by the adventurer Alexander Hare, who set up a harem and retinue of slaves brought from the Malay archipelago. In 1827 John Clunies Ross, a Shetlander, settled on Direction with his family. He and his descendants improved the natural coconut plantations and employed the Malays as labourers. In 1857 the Cocos Islands were taken under British protection and in 1878 placed under the governor of Ceylon. In 1886 George Clunies Ross received from Queen Victoria a grant of the islands in perpetuity; in 1903 the group was made part of the Straits Settlements and incorporated with Singapore.

In World War I men from the German cruiser "Emden" landed on Nov. 9, 1914, to destroy the cable and radio installations on Direction Island. Summoned by radio, the Australian cruiser "Sydney" engaged the "Emden," which was driven ashore in flames on North Keeling Island. In 1945 an airstrip was built on West Island and in 1951 the British government agreed to hand over administration to Australia, subject to the Ross family retaining their property; the transfer took effect in 1955. The airstrip is a stopping place on flights between Perth, Austr., and Johannesburg, S.Af.

**COCTEAU, JEAN** (1889–1963), French poet and writer, whose originality, versatility, and vast output in almost every art form have made his name known throughout the world. The

friend, and often the collaborator, of writers (Blaise Cendrars), musicians (Stravinsky), painters (Picasso), choreographers (Diaghilev), and film workers (Jean Marais), he appears to have found the secret of eternal youth in switching from one "manner" to another.

Born at Maisons-Laffitte, near Paris, on July 5, 1889, of a family of wealthy Parisian lawyers, he was educated at the Lycée Condorcet (1900-04). He attracted attention with his first volume of verse, *La Lampe d'Aladin* (1909). Although medically unfit, he managed, under an assumed name, to follow a regiment of marines to the front in 1914. Transposed, these adventures figure in his novel *Thomas l'Imposteur* (1923; first Eng. trans. 1925). His wartime flights with the aviator Roland Garros inspired many of the poems in *Le Cap de Bonne-Espérance* (1919). His connection with the theatre began with his share in *Parade* (performed 1917), Diaghilev's unorthodox ballet, with music by Erik Satie. Other works in which he collaborated, usually as scenario writer, with composers, include *Le Boeuf sur le toit* (Milhaud), *Les Mariés de la Tour Eiffel* ("Les Six," the group which he helped to form in 1917), *Oedipus-Rex* (Stravinsky), and, in 1959, *Le Poète et sa muse* (Menotti).

After the death of Raymond Radiguet (1903-23), the young prodigy novelist whom he had discovered in 1918, Cocteau took to opium. However, influenced by Jacques Maritain (q.v.), he contributed to the intellectual rehabilitation of Catholicism, and set out to prove that religion and freedom in art are not incompatible (*Lettre à Jacques Maritain*, 1926). A precise description of his disintoxication is given in *Opium* (1930; Eng. trans. 1932).

As a creation of the French avant-garde cinema, his *Le Sang d'un poète* (1932) is a classic of its kind. Of the many films which he wrote or directed, the most memorable are *L'Éternel Retour* (1944), *La Belle et la Bête* (1946), *Orphée* (1950), and *Le Testament d'Orphée* (1960), in which he played the principal part.

In 1935, emulating Jules Verne, he went around the world in less than three months (*Mon Premier Voyage*, 1936; *Round the World Again in 80 Days*, 1937). Later journeys took him to America (1948-49), the eastern Mediterranean (1949), Greece (1952), and Spain (1953 and 1954). In 1956 he visited England, where he received an honorary doctorate at Oxford. He was elected to the Académie Française in 1955. His last years were spent mostly painting (e.g., a triptych for the French church, London), making pottery, and continuing to produce illustrations. He died at Milly-la-Forêt, near Fontainebleau, on Oct. 11, 1963, of a heart attack brought on by the news of the death (on the same day) of his friend Edith Piaf, the French chanteuse.

To Cocteau, his numerous activities were all various forms of poetical expression; the name he gave to his entire work is "poésie." His "poésie de théâtre," for instance, includes *Orphée* (publ. 1927; Eng. trans. 1933), *La Voix humaine* (1930; Eng. trans. 1951; filmed 1947), *La Machine infernale* (1934; Eng. trans. 1936), *Les Parents terribles* (1938; *Intimate Relations*, 1951; filmed 1948), and *L'Aigle à deux têtes* (1946; *The Eagle Has Two Heads*, 1948; filmed 1948). The two studies of adolescence, *Le Grand Écart* (1923; Eng. trans. 1925) and *Les Enfants terribles* (1929; Eng. trans. 1930; filmed 1950), belong to his "poésie de roman"; wishing to disown his early poetry, he dated his literary debut with the publication of his first novel, *Le Potomak* (1919). His weekly articles for *Le Figaro*, collected as *Portraits-Souvenir* (1936; *Paris Album, 1900-1914*, 1956), and the essays of *Le Rappel à l'ordre* (1926; Eng. trans. 1926) are termed "poésie critique." Continuing to write verse throughout his life, he extended his technical experiments to many fields. An extremely prolific and ubiquitous personality, with a taste for paradox and aphorism, he stood, above all, for unconventionality.

**C.O.D.:** see CASH ON DELIVERY.

**COD** are typical fish of the cold- and temperate-water family Gadidae, a group that includes some of the world's most valuable food fishes, the common cod, the haddock and the hakes and pollocks. The common or Atlantic cod (*Gadus morhua*) has three dorsal and two anal fins; the upper jaw projects beyond the lower; the chin has a barbel; the lateral line is pale; and the tips of the ventral fin are not conspicuously prolonged as filamentous feelers. The colour varies considerably through shades of gray green, olive, brown, orange and brick red. They inhabit continental shelf and offshore bank areas across the North Atlantic, on the American side from Cape Hatteras northward to Hudson strait and southern Greenland, and on the European side from the Bay of Biscay to Iceland, West Spitzbergen and Novaya Zemlya. The Pacific cod, which some authorities consider to be a subspecies, *G. morhua macrocephalus*, extends from Oregon on the American side and from Japan on the Asian side northward into the Bering sea.

DOUGLAS P. WILSON

ATLANTIC COD (*GADUS MORHUA*)

Although cods typically live on or near the bottom, at depths ranging from 30 to 250 fathoms or more, cod sometimes swim near the surface when migrating or when pursuing food. They feed on any kind of bottom-living or pelagic invertebrate or fish which is not too elusive for them to catch or too large to swallow. In turn they are preyed upon by larger fishes, especially sharks.

The time of spawning depends on temperature and occurs in some part of the range of the species from November to August. A 40-in. female produces about 3,000,000 eggs a year. The buoyant eggs, 1.10 to 1.82 mm. in diameter, drift with the currents in the plankton community. They hatch in 10 to 50 days, according to temperature, and the young fish continue to drift for several weeks before they descend to the bottom. Their growth rate varies widely. They may average 5 to 8 in. by the end of their first year, 21 to 36 in. by the end of their sixth. The largest specimen caught off North America was over 6 ft. and weighed 211½ lb.; however, commercial catches consist of specimens usually much smaller, from 2½ to 25 lb.

Cod migrate seasonally, northward and into shallower water in summer, southward and into deeper water in late autumn. Fishermen of all northern maritime nations fish for cod, with trawls and hand lines, taking altogether nearly 2,000,000 metric tons a year. Most of the catch is made into frozen filets and fish sticks, or is split, salted and dried. The livers are used in the preparation of cod-liver oil (q.v.), and the eggs or roe are used as ground bait in the sardine fishery of France; a variety of isinglass (q.v.) is made from the air bladder.

Among the other cod fishes are: polar cod (*Arctogadus glacialis*) and Greenland cod (*Gadus ogac*) of the North Atlantic; and saffron cod (*Eleginus gracilis*) of the Pacific.

**CODE.** The word code has many meanings, ranging from the "teen-age" codes found in many secondary schools in the United States to the elaborate civil codes of France, Germany and Switzerland. Its general purport, however, is that of a more or less systematic and comprehensive written statement of rules on a given subject. The rules may or may not be authoritatively promulgated, and the subject may be broad or narrow, but the rules are always written and are always presented in a relatively systematic and comprehensive fashion.

The oldest known code is that of Hammurabi (q.v.). Roman law began with the Twelve Tables and culminated in the code of Justinian, which was given the force of law in A.D. 534 (see ROMAN LAW). The peoples who overran the Roman empire also made codes of law; e.g., the law of the Salian Franks and other Frankish laws (see GERMANIC LAWS, EARLY; SALIC LAW). A famous compilation of rules of maritime law, known as the Rhodian sea

law, was originally put together between A.D. 600 and 800; and various collections of maritime customs, drawn up for the use of merchants and lawyers, acquired great authority throughout Europe in the 14th and 15th centuries (*see* MARITIME LAW).

In modern practice, the ambiguity of the word code is particularly noticeable in the United States, where efforts to bring order out of chaotic masses of statutory law have resulted in different usages.

The basic law of the several states of the United States is, except in Louisiana, the common law—the unwritten rules and principles derived from the decisions and opinions of courts. There are also vast numbers of statutes, ordinances and regulations adopted by legislative and administrative bodies to supplement and change the common law. These laws are ordinarily promulgated in chronological order, with the result that this body of law soon becomes chaotic and unmanageable. Various methods have been devised to put it into orderly and manageable form.

The method most often employed to accomplish this result is the compilation of existing statutory laws of a general and permanent nature, in their current form, into a systematic whole, classified according to subject matter. Repealed, local, special and temporary laws are omitted, and amended laws are included in their latest amended form. The compilation has two chief characteristics. First, the laws included in the compilation are compiled without change in text. Second, the compiled laws are never enacted or adopted as new laws; they may have no official standing whatsoever and at most are given official recognition as presumptive evidence of the current statutory law. Compilations in the United States are usually entitled compiled laws or general laws; but in some quarters, although purists object to the appellation, they are occasionally called codes.

The compilation does not permit the consolidation of similar provisions of different laws or the elimination of inconsistent provisions. And since it is at best only evidence of the law, it does not alleviate the necessity for examining the authentic texts of the laws included in the compilation.

The revision, as distinguished from the compilation, is designed to eliminate these shortcomings. Like the compilation, a revision takes the existing statutory law of a general and permanent nature and organizes it into a systematic whole, classified according to subject matter. But unlike the compilation, a revision is always prepared by authorized officials, changes in the texts of existing statutory laws are made and the revision is always enacted as new law. The magnitude of the textual changes depends upon the reviser's authority and the action of the legislative body that enacts the revision as new law. Sometimes legislative bodies are reluctant to undertake a wholesale revision of all the statutory law. Fearing inadvertent changes and omissions, they prefer piecemeal revisions of the statutory law on particular subjects. But whether wholesale or piecemeal, a revision purports to be a revision of only the statutory law, not the common law.

In the United States, wholesale revisions are usually entitled revised statutes, and piecemeal revisions codes, laws or acts, qualified by a description of the subject matter revised. Sometimes, however, wholesale revisions are called codes, and many of those who object to the use of "code" for compilations regard this usage as entirely proper. In England, different terms are employed: the piecemeal revision is known there as a consolidation, a terminology employed also in New York.

Occasionally, something more comprehensive than a revision is required. Because of conflicts or gaps in the common and statutory law and the need for a comprehensive statement of substantially all the rules of law on a given subject, statutes are enacted embodying for a broad or narrow subject the prevailing statutory and common law with whatever modifications are required in the circumstances. These are usually known as codes, though sometimes as laws (*e.g.*, Negotiable Instruments law) or acts (*e.g.*, Uniform Sales act). In England, the term codification is reserved for legislative enactments of this kind.

**Codification in the United States.**—Codification of law in the comprehensive English sense got under way at an early date in the United States. Early in the 19th century, Louisiana, be-

cause of its French and Spanish law heritage, enacted comprehensive codes, based largely upon the Napoleonic codes. Louisiana enacted a comprehensive civil code in 1824 and a code of practice in 1825. These were the work of Edward Livingston (*q.v.*) and two other jurists. Livingston also prepared a commercial code and the celebrated work called *A System of Penal Law*, which comprised a code of crimes and punishments, a code of procedure, a code of evidence, a code of reform and prison discipline, and a book of definitions. Louisiana, however, did not adopt either of these two comprehensive drafts.

About a decade later in Massachusetts a distinguished commission headed by Joseph Story issued a report favouring the codification of large portions of Massachusetts common law. The commission's recommendations, however, were dismissed with little public controversy. And the great debate over codification of the common law in the United States did not develop until the latter half of the 19th century when David Dudley Field (*q.v.*) engaged in a grand struggle for the codification of New York law.

In New York the movement for codification of the law began smoothly. A code of procedure popularly known as the "Field code," which covered part of the law of civil procedure, was enacted in 1848 with very little dissent (*see* PRACTICE AND PROCEDURE: *United States*). Other drafts of New York codes encountered greater opposition. Objections to the penal code and the code of criminal procedure delayed their enactment until 1880–81, and hostility to the political code and code of evidence led to their defeat. It was Field's civil code that aroused the strongest opposition and touched off the great debate over codification. Field's principal opponent in the debate was James C. Carter, who, as a disciple of a school of historical jurisprudence, decried codification of the common law. After many stormy sessions in the New York legislature the civil code, largely as the result of Carter's influence, was finally defeated in 1886.

Although California and a few other states adopted civil and political codes, the movement for wholesale codification of the common law ended with the decisive defeat of these codes in New York. But codification on a narrower scale continued throughout the United States. Many states enacted codes of civil and criminal procedure, penal and probate codes, and the partial codes represented by some of the "uniform" acts prepared by the National Conference of Commissioners on Uniform State Laws. Perhaps the most comprehensive of these is the Uniform Commercial code prepared by the American Law institute and the uniform-state-law commissioners.

**England.**—The movement for codification was less effective in England than in the United States. Except for such partial codes as the Sale of Goods act, 1893, drafted by Sir MacKenzie Chalmers, England has confined its efforts to the revision and consolidation of its statutory law. Codification was much more successful in British India, where both Field's and Livingstone's works had considerable influence.

**Civil Law.**—In civil-law jurisdictions comprehensive codification of the law is the rule rather than the exception. The movement for codification in these jurisdictions had its effective beginning with the adoption of the five Napoleonic codes of 1803–10, though there were codes on a different scale before that time. The five French codes were the civil code, code of civil procedure, commercial code, code of criminal procedure and penal code. Since then, similar codes, though not always covering the same subjects, have been enacted by most of the nations outside the common-law world. (*See* CODE NAPOLÉON; CIVIL LAW; for more detailed treatment of the codes of the civil-law countries, *see* FRENCH LAW; GERMAN LAW; ITALIAN LAW; JAPANESE LAW; etc.)

**International Law.**—Despite considerable effort devoted to the codification of international public and private law, the results were meagre. Between 1893 and 1928 the Diplomatic Conference of The Hague on Private International Law adopted six conventions, dealing with such matters as marriage and guardianship, but few of them were wholly successful. The International Institute in Rome for the Unification of Private Law prepared drafts of proposed uniform international laws on such matters as arbitra-

tion and the sale of goods; and the International Law commission of the United Nations undertook a series of important studies looking to the codification of various aspects of international law. Greatest success in the codification of international law was achieved in Latin America, where the celebrated Bustamante Code of International Law, prepared by Antonio Sánchez de Bustamante, was adopted by the Sixth International Conference of American States in 1928 and later ratified by 15 countries, 6 without reservation.

Gutteridge, *The Codification of Private International Law* (1951). A list of the best-known codes by name with brief descriptions is included in J. Bouvier, *Law Dictionary*, 3rd rev. ed., vol. i, p. 511 (1914). For additional bibliographical references, see K. Szladits, *Bibliography on Foreign and Comparative Law* (1955) and *Guide to Foreign Legal Materials* (1959).

(R. C. McC.)

**CODEINE** occurs naturally in opium, being one of the alkaloids (*q.v.*) of the phenanthrene group and a derivative of morphine (*q.v.*), retaining in a modified form the characteristic physiological action of the latter. It is commonly used orally in cough sirups and hypodermically to relieve pain, spasm and as a sedative. It crystallizes with one molecule of water, in large translucent prisms, and behaves as a monoacidic base forming salts of which the sulfate and the phosphate are those most frequently used in medicine.

(F. L. A.; X.)

**CODE NAPOLÉON.** The Code Napoléon (French civil code) was enacted into law on March 21, 1804, under the title Code Civil des Français. This title was changed to Code Napoléon in 1807 to honour Napoleon I, the emperor who, as first consul of the republic, had taken active interest in the drafting and had brought to completion this monumental legislative undertaking. With the fall of the Napoleonic regime, the original title was restored in 1816. Reference to Napoleon was reinstated in the title of the code in 1852 by a decree of Louis Napoleon (Napoleon III), then president of the French republic. Since Sept. 4, 1870, however, statutes have referred to it simply as the "civil code."

**Forces Behind Codification.**—The demand for, and the beginning of, codification in France preceded the Napoleonic era. For centuries the law had been unwieldy in bulk and uncertain in form; diversity of laws was the dominant characteristic of the prerevolutionary legal order. Roman law governed in the south of France, while in the northern provinces, including Paris, a customary law had developed based largely on feudal Frankish and Germanic institutions. Marriage and family life were almost exclusively within the control of the church and governed by canon law. In addition, starting with the 16th century, a growing number of matters were governed by royal decrees and ordinances and by a case law developed by the *parlements* (supreme courts). As Voltaire put it, the traveler in those days changed laws as often as he changed horses! Further, the law was full of obsolete rules, and important questions that had been debated for centuries were still unresolved. People complained that the law was so confused that nobody, including the judges, was able to know it with certainty. The courts had become very unpopular and aphorisms such as "God save us from the justice of the courts" were common. Thus, even before the Revolution the states-general had expressed their wish for new and uniform national legislation. Vested interests, however, blocked such codification since it was apparent that reform would necessarily encroach on their privileges.

After the Revolution, codification had not only become possible but almost necessary. Powerful control groups such as the manors and guilds had been destroyed; the secular power of the church had been suppressed; and the provinces had been transformed into subdivisions of the new national state. On the other hand, the Revolution had strengthened the nation's consciousness of unity and had resulted in a thorough political unification of France which, in turn, demanded a new body of law uniform for the en-

tire state. The demand for codification was also in accord with current ideas concerning the purpose and function of law in society, namely, the conviction that the main role of the law ought to be the preservation of the social status quo. The achievements of the Revolution could and should be consolidated in an authoritative and enduring text in the form of a code. In connection with these ideological trends, Napoleon's personal aspirations and the attitude of powerful Jacobin groups should also be mentioned. Napoleon's vivid interest in codification has been explained partly as the result of a well-known rivalry with monarchical absolutism and partly due to the influence of Rousseau. Indeed, Napoleon was an admirer of Rousseau who, along with other 19th-century philosophers, considered legislation as the most important governmental activity and the legislator as a mold of men and states. The Jacobins, also influenced by Rousseau, regarded legislation as a good in itself, enabling every man to comprehend "the principles of conduct" in a social milieu.

**The Process of Codification.**—Giving expression to a widespread popular feeling and to the needs of the revolutionary government, the constituent assembly of 1790 adopted a unanimous resolution providing that "There shall be a code of civil laws common for the entire realm" (Sept. 4, 1791). Further steps toward the actual drafting of a civil code, however, were first taken by the National Convention of 1793, which established a special commission headed by the duc de Cambacérès and charged it with the task of completing the project within a month. This commission prepared within six weeks of its creation a draft code consisting of 719 articles. Though truly revolutionary both in intent and content, the draft was rejected by the convention on the ground that it was too technical and detailed to be easily understood by all citizens. A second, much shorter draft of 297 articles (1794) was little debated and had no success. Cambacérès' persistent efforts produced a third draft (1796), containing 500 articles, which was equally ill fated. Another commission, established in 1799, presented a fourth scheme prepared in part by Jean Ignace Jacqueminot. Finally, the consulate, with Napoleon Bonaparte as first consul, resumed the legislative work, and a new commission was nominated. A final project was pushed forward until it received definitive form in a draft submitted first to the legislative section and then to the plenary assembly of the newly created council of state (*conseil d'état*). There it was minutely discussed, and with the steadfast participation and vigorous support of Napoleon as chairman it was enacted into law piecemeal, in the form of 36 statutes passed between 1801 and 1803. On March 21, 1804, these statutes were consolidated in a single body of law—the Code Civil.

**The Code as Rational Legislation.**—The Code Napoléon was superior to all prior enactments also referred to as "codes" by virtue of its ideological premises and formal qualities. Pre-Napoleonic codifications, such as the Justinian legislation (*Corpus juris civilis*) and the Prussian code of Frederick the Great (*Allgemeines Preussisches Landrecht*), were systematic compilations of statutes, customs and judicial decisions that intended to coordinate and restate pre-existing law rather than to supersede it completely. The chief purpose of the Justinian legislation was to achieve, without significant alterations, an orderly arrangement of the law, convenience of ascertainment and general accessibility to the public. Similarly, the code of Frederick the Great was conceived, in accordance with natural-law ideas of an enlightened despotism, as an authoritative legislative restatement of the law in the form of specific rules prescribing definite legal consequences for all foreseeable sets of facts. The Code Napoléon, on the other hand, was conceived as a complete legislative statement of principles rather than rules and as a truly revolutionary enactment designed to remake the law in the image of a new and better society. It was founded on the premise that for the first time in history a purely rational law should be created, free from all past prejudices and deriving its content from "sublimated common sense;" its moral justification was not to be found in ancient custom or monarchical paternalism but in its conformity with the dictates of reason. And thus its fundamental precepts are presented with the claim of universality, namely, as an assertion that

a legal order is legitimate only when it does not contradict such precepts.

One of the most important characteristics of the code as a product of rational legislation is its reliance on reason and logic as essential factors in the judicial process. Human reason, according to the prevailing rationalistic philosophy, had the inherent ability to regulate all legal relations. Consequently, a code could and should be complete in its field and self-sufficient; it should lay down general principles in accordance with a logical scheme; and it should have such inner consistency that logical reasoning should furnish answers to all questions arising within its framework. Resort to other sources or to any other method of implementing its provisions should be excluded, and the judge should never refuse to give judgement on the ground that the law is obscure or that the question in hand is not answered by the code. All apparent gaps ought to be filled by logical reasoning and by analogy from other provisions. Thus, in spite of the early revolutionary trend that tended to strip the courts of any power except a literal application of the statute, the code succeeded in balancing the function of the legislature with that of the courts.

The formal qualities of the code elevate it to the position of one of the most elegant achievements of juristic thought. The code possesses an extraordinary measure of lucidity and is almost completely free from the intrusion of nonjuristic elements, confusing casuistry and sterile abstractions. Its legal precepts have a tangible clarity; the definition of legal concepts was avoided except in a comparatively small number of instances; and qualifications, limitations and exceptions were kept to a bare minimum. Numerous provisions sound epigrammatic and have become part of common parlance in France as legal proverbs. Provisions such as "A contract properly concluded takes the place of law for those who have made it" (art. 1134) and "Every act of man which causes harm to another binds the one through whose fault it has occurred to repair it" (art. 1382), forming respectively the foundation of contractual and delictual liability, may sacrifice juristic precision to vivid form, but at the same time express legal concepts in the everyday language of the French people and furnish to laymen a comprehensible standard of conduct.

**Contents.**—The Code Civil has been described as an effort "to consolidate the achievements of the Revolution, to reconcile the customary law with the Roman law, and to effect a smooth transition from the past to the present." The substantive provisions of the code thus represent a fusion of revolutionary ideas with the customary law of the northern provinces, expressed in the conceptual technique of 18th-century Roman law. To achieve that end, the drafters relied heavily on the work of earlier commissions and on the extensive writings of two great jurists of previous generations, R. J. Pothier (1699–1772) and J. Domat (1625–96), who had laid the foundations for a uniform French law. Pothier had laboured to establish an "area of agreement" between conflicting local customs and to digest them in the form of a "customary common law." Domat, on the other hand, had contributed to the development of a conceptual technique and the simplification of the Roman law then prevailing in the southern provinces.

Under the code all citizens are equal: primogeniture, hereditary nobility and class privileges are extinguished; civilian institutions are emancipated from ecclesiastical control; freedom of the person, freedom of contracting and inviolability of private property are fundamental principles. Yet its provisions strike a successful balance between a "prudent liberalism" and an "enlightened conservatism" rather than pushing revolutionary claims to an extreme. The revolutionary and the traditional outlook, the old and the new, were successfully combined in a spirit of moderation and as an organic whole. This balance of conflicting values was the philosophy of J. É. M. Portalis, one of the main drafters, who wrote: "The spirit of moderation is the true spirit of the legislator; the political and the social good is always found between two extremes."

The 2,281 articles of the Code Civil are systematically arranged in a preliminary title dealing with law and its application in general, and in three "books" dealing with the law of persons, the law of things and the methods of acquiring rights.

**Law of Persons.**—The first book of the code deals with the enjoyment of civil rights, the protection of personality, domicile, guardianship, tutorship and curatorship, relations of parents and children, marriage, personal relations of spouses and the dissolution of marriage by annulment or divorce.

The drafters of the code regarded the family unit as the fundamental institution in a civilized society. Accordingly, though preserving the revolutionary conceptions of secularized marriage and family life, they laboured to strengthen family ties. According to the code, the husband is the chief of the family and the wife owes him obedience. In the absence of other marriage settlement, movables owned by the parties at the time of marriage and all acquisitions during marriage form a community fund; this fund as well as the separate property of the wife are managed by the husband. Originally, the wife was practically incapable of any act in the economic sphere without the written consent of her husband; her condition, however, was drastically changed by a number of statutes which placed the spouses on an almost equal basis. Freedom of divorce, which prevailed during the Revolution, was substantially limited by the code and became available only on certain grounds. The relevant articles of the code were repealed in 1816 and divorce was reintroduced only in 1884.

**Law of Things.**—The second book of the Code Civil regulates property rights: ownership, usufruct and servitudes. Feudalism, as a hierarchy of persons tied to a hierarchy of lands, could have no place in the code. Accordingly, the predominant relationship between persons and things is ownership, which is a complete, free and almost absolute right. Usufructs and servitudes are permissible but cannot involve a personal duty; they are simply charges "laid on an estate for the use and utility of another estate belonging to another owner" (art. 637). The code imposes certain limitations on real-estate ownership to guarantee to adjoining owners the normal enjoyment of their property. In addition to these "neighbourhood rights," restrictions on property have been imposed by eminent domain exercised in the interest of the public and by judicial expansion of the notion of abuse of right.

**Acquisition of Rights.**—The third book of the code deals with the methods of acquiring rights by succession, donation, marriage settlement and obligations. In the last chapters, the code regulates a number of nominate contracts, legal and conventional mortgages, limitation of actions and prescription of rights.

In the field of succession, freedom of disposition is limited in favour of surviving children and by public-policy considerations relating to the prohibition of fideicommissa (bequests which the donor asks the recipient to transfer to another). Wills may be holographic, secret or publicly declared. In the absence of a will the estate devolves to blood relatives in accordance with a well-defined order of succession, and the surviving spouse is called to inherit only in the absence of blood relatives up to the 12th degree.

With regard to obligations, the law establishes the traditional Roman law categories of contract, quasi contract, delict and quasi delict. Freedom to contract is not spelled out explicitly but is an underlying principle in many provisions. The law of contract reflects in general a highly individualistic spirit, and limitations on contractual freedom arise mostly from general considerations of public policy.

The code reflected the social facts of 1804 and could not possibly have continued unchanged into the 20th century. Thus, in the long period in which it has been in force the code has been modified by a large number of statutes, and a body of case law has grown around its provisions. Further, a number of important statutes enacted during the 19th and 20th centuries, though bearing on civil-law matters, were left outside the code. Technical views about codification have also changed, and thus revision came to be regarded as highly desirable in France. In 1904, after the celebration of the code's centenary, a commission was nominated to prepare a revision. In 1945 a new commission was charged with the preparation of a complete revision, and its work is published annually in special volumes.

**Dissemination of the Code.**—The code was originally introduced into areas then under French control: Belgium, Luxem-

bourg, the German territories on the left bank of the Rhine, the Palatinate, Rhenish Prussia, Hesse-Darmstadt, Geneva, Savoy, the duchies of Parma and Piacenza, Piedmont and the principality of Monaco. As the armies of Napoleon swept through Europe, the code was introduced into the newly conquered territories: in Italy, the Netherlands, the Hanseatic territories and the grand duchy of Berg. Napoleon's victories opened the door to the code even beyond the conquered territories; through direct persuasion, exercised by Napoleon personally and by his envoys, the code was introduced in Westphalia, Hanover (united to Westphalia in 1810), the grand duchies of Baden, Frankfurt and Nassau, the free town of Danzig, the grand duchy of Warsaw (a part of Russian Poland), several Swiss cantons and in the Illyrian provinces. As the backbone of the code was Germanic custom enacted in accordance with the conceptual technique of 18th-century Roman law, its expansion did not meet great resistance; several of these territories did not even associate the Code Civil with French imperialism and actually preserved it for a long time after the fall of the empire. The code thus remained in force in those parts of Germany situated on the left bank of the Rhine, in the grand duchy of Baden, and in a small sector of the Rhine province east of the Rhine until 1900; in Geneva until 1912; and in Belgium, Luxembourg and Monaco until the present time.

During the 19th century the Code Napoléon was voluntarily adopted in a number of European countries either in the form of simple translation or with considerable modifications. Thus in Italy the civil codes of the two Sicilies (1819), Parma (1820) and Modena (1852) and the Albertine code of Sardinia (1837) derived directly from the Code Napoléon. The Italian civil code of 1865, enacted after the unification of Italy, had as its model the Albertine code—and thus a close, though indirect, relationship with the Code Napoléon. The new Italian code of 1942 has to a large extent departed from this tradition.

In the Low Countries, the Dutch civil code of 1838 preserved much of the spirit, content and legislative technique of the Code Napoléon. In the mid-20th century, however, revision was underway which indicated the possibility of recodification along different lines. In the Balkan peninsula the civil code of the Ionian republic (1842) was largely modeled after the Code Napoléon, while the civil code of Rumania (1864) was practically a free translation of the French original. Finally, in the Iberian peninsula, the civil codes of Portugal (1867) and Spain (1889) had as their main source the Code Napoléon.

Further, the Code Napoléon has become the foundation of several codes of the new world. In Louisiana, the only civil-law state in the U.S., codification of civil law was attempted as early as 1808. It is not known whether the drafters of that early codification possessed the definitive text of the Code Napoléon, but divergencies from the latter were not very great. The Louisiana civil code of 1825 (revised in 1870 and still in force) is clearly and closely connected with the Code Napoléon. Civil codes enacted during the same period in other states of the U.S. had nothing in common with the Code Napoléon since they were essentially compilations of common-law materials and restatements of the law rather than codes in the continental sense. Such codes had as their prototype a draft civil code prepared for the state of New York by David Dudley Field in 1862. In Canada, the civil code of Quebec (1866) was largely based on the Custom of Paris; however, it displays a great similarity to the Code Napoléon with regard to both legislative technique and substance.

In Latin America, the Code Napoléon was introduced in French in Haiti (1825) and in the Dominican Republic (translated into Spanish in 1884) and is still in force there. The civil codes of Bolivia (1830) and Chile (1855) followed closely the arrangement of the Code Napoléon and borrowed much of its substance. The Chilean code was in turn copied by Ecuador (1857) and Colombia (1873) and closely followed by Uruguay (1868) and Argentina (1869). The civil codes of Puerto Rico and the Philippines are related to the Code Napoléon only indirectly, reproducing with slight amendments the Spanish civil code of 1889.

In the near east, the Egyptian codes of 1875 and 1883 and the civil code of Lebanon (1934) were founded directly on the Code

Napoléon. The new Egyptian civil code of 1948 did not completely depart from the French tradition. Finally, in the far east a draft code prepared by the French jurist G. E. Boissonade along the lines of the Code Napoléon was applied in Japan from 1880 to 1896 even without legislative approval.

The influence of the Code Napoléon diminished at the turn of the century as new types of codification were started with the introduction of the German civil code of 1896 and the Swiss civil code of 1912. The logical rigour of the former and simplicity of the latter offered a certain attraction; Turkey adopted the Swiss civil code in translation (1926) and Japan the German civil code with significant alterations (1898). The codes of Brazil (1916), Mexico (1928), Peru (1936), pre-Communist China (1931) and Greece (1940) were largely products of a comparative method; ideas borrowed from the German, French and Swiss civil codes were successfully combined with indigenous institutions. However, in spite of all modern tendencies, and after more than a century and a half since its promulgation, the Code Napoléon is still living law in a great part of the world. History has thus partly justified the melancholic words uttered by Napoleon in exile: "My real glory is not the forty battles I won, for Waterloo's defeat will destroy the memory of as many victories . . . What nothing will destroy, what will live forever, is my Civil Code."

CODES AND CIPHERS: see CRYPTOLOGY.

**CODEx**, the name given to the earliest forms of manuscript in book form (i.e., the collection of written pages stitched together) which replaced the earlier roll of papyrus and the wax tablets (which when hinged or bound together formed the first codex or caudex); also the Latin form of the English word "code" (*q.v.*), meaning a body of law or regulations. For examples of famous codices, see the articles BIBLE; LIBRARY; and PALEOGRAPHY.

**CODIAEUM**, a small genus of Indo-Malayan shrubs belonging to the family Euphorbiaceae (*q.v.*). One species, *C. variegatum*, a native of Polynesia, is cultivated in many varietal forms as an ornamental or potted plant under the common name of "croton" for its magnificently variegated leaves.

**CODINUS, GEORGE** (GEORGIOS KODINOS CUROPALATES) (fl. probably late 15th century A.D.), was wrongly credited with the authorship of certain Byzantine topographical and historical works:

1. *Patria*, divided into five sections: (a) the foundation of Constantinople; (b) its topography; (c) its works of art and sights; (d) its buildings; (e) the construction of the church of Hagia Sophia. Written and revised in the earlier Macedonian and Comnenian periods this was perhaps copied by Codinus, whose name it bears in some (later) manuscripts. The chief sources are: the *Patria* of Hesychius Illustrius of Miletus, an anonymous *Brief Chronological Record* (c. 750), and an anonymous account of Hagia Sophia (ed. by T. Preger in *Scriptores originum Constantinopolitanarum*, fasc. I; 1901). Other sources appear to have been Procopius' *De Aedificiis* and the poem of Paulus Silentarius on the dedication of Hagia Sophia.

2. *De Officiis*, an account of court and higher ecclesiastical dignities and ceremonies (*cf.*, *De ceremoniis aulae Byzantinae* of Constantine Porphyrogenitus). This probably comes from the mid-14th century and is a valuable source for late Byzantine administrative history.

3. A chronological outline of events from the beginning of the world to the taking of Constantinople by the Turks.

**CODLING MOTH** (*Carpocapsa pomonella*), a small dark gray moth, the larva (a pinkish-white caterpillar) of which is very destructive to apples and other fruit. Indigenous to Europe, it has spread, through the agency of commerce, wherever the apple is cultivated.

The most effective methods of moth control are by binding the tree trunks with chemically treated paper or sacking and by spraying the top growth with lead arsenate when most of the petals have fallen.

**COD-LIVER OIL** (*OLEUM MORRHUAE*), the oil obtained from the liver of the Atlantic cod (*Gadus morrhua*) and other species of the family Gadidae. The chief producing countries are England, Norway, Iceland and Canada. The oil is made by steam, water, acid or alkali digestion of fresh livers. Alkaline digestion appears to be the best method based on vitamin A recovery. Medicinal grades are subsequently destearinated by chilling and filtering off the congealed "stearine." The "stearine" fraction contains fatty acids other than stearic acid; therefore, it is not a true stearin.

Chemically, cod-liver oil is a typical marine animal oil. It is a mixture of glycerides of many fatty acids, of which the unsaturated fatty acids oleic acid, gadoleic acid and palmitoleic acid predominate. Since it is high in unsaturated fatty acids, it is subject to oxidation and the development of rancidity and destruction of vitamin A when exposed to air. Deficiencies of vitamins A and E have been observed in animals fed rancid cod-liver oil; this can be counteracted in some instances by feeding vitamin E.

In the 19th century cod-liver oil was a folk remedy for wasting diseases. During the period 1914-22 its medicinal value was clinically established and related to the presence of vitamin A and especially vitamin D. These vitamins comprise only a minute fraction of the oil, and the content is usually expressed in units; average oil contains 1,400 international units (I.U.) of vitamin A and 100 I.U. of vitamin D per gram (0.30 micrograms of crystalline vitamin A alcohol = 1 I.U.; 0.025 micrograms of crystalline vitamin D<sub>3</sub> = 1 I.U.). The vitamin potency varies considerably for different species; it increases with the age and varies inversely with the fatness of the liver.

Cod-liver oil is a specific for rickets and other disorders of calcium metabolism resulting from a lack of vitamin D. Its dietary usefulness is related to both its vitamin D and vitamin A potency, primarily in poultry feeds but also in feeds for other animals. The high content of certain unsaturated fatty acids may become an important aspect in nutrition.

Other fish oils have also been developed as vitamin sources. Halibut, rockfish, dogfish and soup-fin shark liver oils are outstanding sources of vitamin A. Halibut-liver oil has approximately ten times the potency of cod-liver oil, while the liver oils of the percomorph fishes (tunas, mackerels, swordfishes and sea basses) often contain 100 times as much vitamin A and D as cod-liver oil. These oils, and oily solutions of vitamin A, D<sub>2</sub> and D<sub>3</sub>, have surpassed cod-liver oil as vitamin sources in human medication.

See H. J. Deuel, Jr., *The Lipids, Their Chemistry and Biochemistry*, vol. i (1951).

**CODREANU, CORNELIU ZELEANU** (1899-1938), founder of the Rumanian terrorist Iron Guard, was born at Iasi on Sept. 13, 1899, his father being of Polish-Ukrainian origin, his mother German. At Iasi university Professor A. C. Cuza inspired him with anti-Semitic ideas, and in 1923 Codreanu founded the anti-Semitic National Christian league, with avowed terrorist aims. He was arrested at Iasi in 1924 and on regaining freedom murdered the police prefect responsible. Tried in 1925 and acquitted amid popular acclaim, he went abroad. Returning to Rumania in 1927, he renamed his organization Legion of the Archangel Michael and made pilgrimages through the countryside in national costume on a white horse. In 1928 he joined his group to M.

Steleescu's similar Brothers of the Cross, renaming it the Iron Guard, with himself as captain. The Guard gained five seats in parliament in 1932 but was dissolved in 1933 by the Liberal prime minister I. G. Duca, who was then assassinated by Guardists.

With the rise of Naziism, Codreanu became closely associated with Germany, parting over this issue from Stelescu, who publicly denounced the Guard and was then murdered in hospital (1936). Codreanu's party, now Everything for the Fatherland, secured about 16% of the votes in the 1937 elections but was dissolved on the establishment of King Carol's dictatorship. A. Calinescu, minister of the interior, had Codreanu imprisoned in May 1938, and on Nov. 30 Codreanu and 13 comrades were shot, according to the official version, while trying to escape in transit between two prisons.

(B. Br.)

**CODRINGTON, SIR EDWARD** (1770-1851), British admiral, belonged to a family long settled at Dodington in Gloucestershire. He entered the navy in 1783 and was promoted lieutenant in May 1793. Lord Howe selected him to be signal lieutenant of his flagship, the "Queen Charlotte," at the battle of the Glorious First of June, 1794. He was promoted commander after the action and captain in 1795, in which capacity he commanded the "Babet" frigate in Lord Bridport's action off Lorient. Between 1797 and 1805 he was unemployed and married in 1802 Jane Hall of Kingston, Jamaica. In 1805 he was appointed to the "Orion" (74 guns) and was selected by Nelson to command the rear squadron at the battle of Trafalgar. As this did not materialize, his ship fought in Nelson's column. In 1809 he was captain of the "Blake," flagship on the Walcheren expedition. Thereafter he served on the east coast of Spain and then, in the war of 1812-14, was active in North American waters during the operations against Washington, Baltimore and New Orleans. He became rear admiral in 1814, vice-admiral in 1821 and was appointed to the command of the Mediterranean fleet of 13 sail in 1827, flying his flag in the "Asia" (84 guns). In June 1827 he sailed to the Levant to command the allied fleet which at the battle of Navarino (*q.v.*) on Oct. 20 decided the independence of Greece by the destruction of the Ottoman fleet. During the period of his command the Aegean and the Adriatic were cleared of those pirates who had long been a menace to shipping in those parts. His victory at Navarino was the culminating event of his life, but it was received with mixed feelings in London, where it was officially described as "an untoward event" since it was held that Codrington had exceeded his instructions and that the diplomatic consequences were serious and unwelcome. The lord high admiral, the duke of Clarence, defended Codrington in the protracted correspondence which ensued, but he was recalled in June 1828, shortly before the Morea was finally evacuated by the Egyptians. On his return he published a justification of his conduct and in 1831 was employed again in the channel, serving as commander in chief at Portsmouth from 1839 to 1842. He died on April 28, 1851.

He left two sons who distinguished themselves, Sir William John (1804-84) as a soldier in the Crimea and Sir Henry John (1808-77) as admiral of the fleet.

See Lady Bouchier, *Memoir of the Life of Admiral Sir Edward Codrington*, 2 vol. (1873); C. G. Pitcairn Jones (ed.), *Piracy in the Levant, 1827-28; selected from the papers of . . . Codrington*, Navy Records Society (1934).

(C. C. L.)

**CODRUS**, in Greek legend, the last king of Athens, son of Melanthus, of the Neleid family of Pylos, who came to Athens as a refugee. It was prophesied at the time of the Dorian invasion of the Peloponnesus (11th century B.C.?) that only the death of their king at the enemy's hands could ensure victory to the Athenians. Codrus therefore made his way disguised into the enemy's camp and provoked a quarrel, in which he was killed. The Dorians, on discovering this, retreated. The Athenians thought no one worthy to succeed Codrus and abolished the title of king, substituting that of archon (another version says that his son Medon was the last king). The royal families of Ionia as well as the Medontidae, the ruling family in Athens, claimed descent from Codrus. Codrus had a shrine in Athens, together with Neleus and Basile.

**CODY, WILLIAM FREDERICK** (1846–1917), U.S. frontiersman and showman, known as "Buffalo Bill," was born on a farm in Scott county, Ia., on Feb. 26, 1846. He had very little schooling but before the end of his teens he had worked as horse wrangler and mounted messenger for a large western wagon-freight firm, as a luckless prospector in the Pikes peak gold rush and as a pony express rider. During the American Civil War, Cody served the Union as scout for the 9th Kansas cavalry in a campaign against Kiowa and Comanche Indians and was a U.S. army scout in Tennessee and Missouri military operations.

He married Louisa Frederici in St. Louis in 1866 and the following year became a buffalo hunter for the firm of Goddard Brothers, then under contract to provide food for Kansas Pacific railroad construction crews. It was for his great success as a hunter that Cody won his lasting nickname "Buffalo Bill." Using a .50-calibre breech-loading Springfield rifle he killed (by his own count) 4,280 buffaloes during a period of 17 months.

During 1868–72, and again in 1876, Cody resumed duties as a U.S. army scout in campaigns against the Indians. While serving George A. Custer against the Sioux and Cheyennes in 1876, Cody killed and scalped Yellow Hand, a Cheyenne chief, in a duel. In this engagement Cody felled Yellow Hand with his rifle and within seconds, in the scout's own words, "I . . . had driven the keen-edged weapon to its hilt in his heart. Jerking his war-bonnet off, I scientifically scalped him in about five seconds." A popular dime-novel press gave varying accounts of this duel which stirred the reading public.

The dime novels, especially those of Ned Buntline (pen name of E. Z. C. Judson) featuring semifictional "Buffalo Bill" exploits, gave Cody a world-wide notoriety. Cody was a superb showman and in 1872 took the leading role in a play based on his exploits. In 1883 he organized a "Wild West" exhibition—a spectacular show that was successfully staged in the United States, Great Britain and on the continent. Among the star performers in this show was Annie Oakley, famed rifle shot; for a brief period Chief Sitting Bull also toured with the troupe.

Cody made a fortune in the show business but invested his money unwisely in various speculative ventures. On Jan. 10, 1917, Cody died and was buried in a tomb blasted from solid rock on Lookout mountain, 20 mi. from Denver, Colo.

**BIBLIOGRAPHY.**—*The Life of Hon. William F. Cody Known as Buffalo Bill*, an autobiography, has been published in several editions. See also Richard J. Walsh, *The Making of Buffalo Bill: A Study in Heroics* (1928); Rupert Croft-Cooke and W. S. Meadmore, *Buffalo Bill: The Legend, the Man of Action, the Showman* (1952); Henry Blackman Sell and Victor Weybright, *Buffalo Bill and the Wild West* (1955). The last-named item is excellent pictorially.

(O. O. W.)

**COEDUCATION**, the education of girls in the same schools that boys also attend, is a modern phenomenon. Plato favoured a parallel education for men and women and proposed that young children play supervised educational games together, but Athenian girls were generally taught in the household by mothers and nurses and Aristotle's view that the distinctive function of females required a different education became dominant. Sparta trained boys and girls separately. In the age of Hellenism girls were segregated. In Rome coeducation probably existed for the children of the privileged classes only through the early years of primary instruction.

Coeducation was adopted earlier and more widely in the United States than in Europe, where tradition proved a greater obstacle. Many advocates of equality for girls accepted separate schools, especially at the secondary level, so long as the same subjects were taught in the same way and equal opportunities were provided for vocational and university preparation. Antagonism to coeducation in England and on the continent diminished more rapidly in higher education than in secondary. In England Girton (Cambridge) was established for girls in 1869 (see DAVIES, (SARAH) EMILY) and the London School of Economics was opened to women in 1874. Germany permitted women to matriculate in 1901 and by 1910 women had been admitted to the universities of Holland, Belgium, Denmark, Sweden, Switzerland, Norway, Austria-Hungary, France and Turkey.

**History.**—The history of coeducation is, of course, a part of the over-all story of the long struggle to achieve equal rights including equal educational opportunities for women. From the dawn of the middle ages to the late 18th century social usage in western Europe separated the education of the sexes except among a few Protestant groups after the Reformation, when Luther and other leaders urged that girls as well as boys should be taught to read the Bible. The resulting tendency toward coeducation became especially marked in Scotland and the northern parts of England and in colonial New England, where young children of both sexes attended dame schools and, in the latter half of the 18th century, girls were gradually admitted to town schools. In New Netherland, Dutch parochial schools admitted boys and girls "at least until they learned to read." In Quaker settlements boys and girls generally attended school together; the Friends in England as well as in America were pioneer proponents of coeducation as they were of universal education. German communities in North America favoured separate education for boys and girls. After the American Revolution educational reform, based on ideals of democracy, equality and freedom, challenged parochial education, and the new free public elementary, or common, schools, which supplanted church institutions in the late 18th and early 19th centuries, were almost always coeducational. By the end of the 19th century only a few larger common-school systems in cities had separate schools for girls.

At the secondary level, colonial Latin grammar schools had accepted boys only, and the earliest academies and seminaries separated the sexes. The first high schools also segregated the sexes, but the trend toward coeducation became dominant after the Civil War. By 1900 almost all public high schools were coeducational.

Collegiate education followed the same course in regard to coeducation. Oberlin (O.) college admitted women to college classes in 1837. Hillsdale (Mich.) college (founded 1844) gave its first A.B. degree to a woman in 1852. Coeducational from the beginning were Albion (Mich.) college (1850); Antioch college, Yellow Springs, O. (founded 1852), led by Horace Mann; Eureka (Ill.) college (1855); Earlham college, Richmond, Ind. (1859); and Swarthmore (Pa.) college (1864).

State universities, led by those in the middle west, followed the example of private colleges in respect to coeducation. The State University of Iowa, Iowa City, granted a bachelor's degree to a woman in 1863. At the University of Wisconsin, Madison (1850), all departments were declared open to women in 1866. The University of Michigan, Ann Arbor, was opened to women in 1870. Numerous older colleges admitted women during the 1870s; by 1880 more than 50% of U.S. colleges were coeducational, and by the end of the century the proportion exceeded 70%. Tulane, Columbia, Brown and Harvard avoided coeducation but opened affiliated women's colleges between 1887 and 1894.

Professional schools were reluctant to admit women and professional associations opposed women's practice (see WOMEN, LEGAL POSITION OF), but resistance crumbled in most professions in the latter half of the 19th century. The Geneva Medical school of western New York (now Hobart college) gave Elizabeth Blackwell an M.D. degree in 1849. Lemma Barkaloo entered the law school of Washington university, St. Louis, Mo., in 1869. At Oberlin, Antoinette Brown Blackwell finished the theological course in 1850, and Hartford Theological seminary was opened to women in 1889. Postgraduate schools, developing after 1876, have been open to both sexes, although few women applied for entrance before the end of the century. Johns Hopkins university, Baltimore, Md., a pioneer in graduate study, did not admit women till 1907.

**Roman Catholic Position.**—Coeducation was accepted very slowly in Roman Catholic colleges and universities in the United States, but by the late 1920s woman students were accorded full status in many of them. Traditional policy, while approving coeducation for young children, has opposed coeducation for adolescents. Economic and social advantages of coeducation are held to be offset by physiological, vocational and moral considerations. The attitude of the church was expressed in an encyclical of

Pius XI, *Rappresentanti in terra* (1929), Latin text, *Divini illius Magistri* (1930), which described coeducation as "founded upon naturalism and the denial of original sin." In the United States the original position of the church on the separate education of the sexes at all levels was modified somewhat, in part because great waves of immigration made it impossible for the small number of teachers to care for boys and girls in separate schools. By the second half of the 20th century nearly all Catholic parochial primary schools and 54% of Catholic high schools were coeducational.

**Support and Opposition.**—Supporters of coeducation in public elementary schools in the United States stress the justice it accords both sexes, its economy and convenience, its helpful effect on manners and morals and its stimulus to study. Opponents of coeducation at the elementary level have argued that girls' nature is so different from that of boys that a different kind of education is required, especially from the age of 12. The discussion of the question has been more heated at the secondary and higher levels where opponents argue that to have boys and girls in the same school damages the study habits of both and makes necessary a curriculum that fits neither sex and lowers academic standards. Some have charged that coeducation endangers the health of girls and that the enforced association of young men and women encourages too early marriages. In reply, the advocates of coeducation have claimed that young men and women work together better in later years when they have had the experience of studying together and that women have many legitimate vocational aims which can be served only through study at a coeducational institution.

The growth of coeducation in the United States has been favoured by the movement for women's rights, the rapid growth of the secondary school system, the demand for teachers who could create an educated electorate, the employment of women outside the home and in almost every occupation and profession, a phenomenal rise in the college population, the rising rate of marriage of students still in college and the pronounced preference of young men and women for coeducation.

**World Survey.**—*Commonwealth of Nations.*—There has never been any official policy about coeducation in England and Wales. In the public system of elementary education which grew up during the 19th century about half the schools were mixed, but this was almost exclusively for reasons of economy or numbers and in many cases it was coinstruction rather than coeducation which was practised, the girls sitting on one side of the room and the boys on the other and separating for play and other activities outside the classroom. Similarly, when the Education act of 1902 introduced a public system of secondary education, many mixed secondary schools were built, again largely for reasons of economy rather than principle. In Wales the proportion of mixed schools has always been much higher than in England, in part at least because of the sparsity of population outside the industrial areas. The general feeling was expressed in 1945 by the ministry of education, which wrote: "It is neither possible nor desirable to lay down a fixed doctrine. . . . In the fields of primary and further education, co-education is to be preferred. It is in the secondary field that the rival advantages of separation make themselves most apparent." The great majority of primary schools are mixed, but secondary schools, whether grammar, modern or technical, exist in each of the three categories: boys', girls' and mixed schools.

The English public schools have always been exclusively for boys. Most private schools and especially private boarding schools are for boys or for girls only. There are a few notable exceptions, such as Bedales, which was founded as a boys' school in 1893 but admitted girls in 1898. Another well-known coeducational boarding venture is Dartington Hall, founded by W. B. Currie. The Society of Friends maintains a sizable group of coeducational boarding schools in England.

Most of the teacher-training colleges of England had been for men or women only but after World War II the policy was to encourage mixed colleges. Other establishments for higher education in the United Kingdom are open to both sexes, although at

Oxford and Cambridge women have been admitted only recently and to a limited extent.

The Scottish tradition, as indicated above, is quite different from the English; coeducation has been almost universally practised in Scotland since the 17th century, and most primary and secondary schools in Scotland are mixed. The rule is broken here and there in large cities but rarely elsewhere, except in the handful of public schools on the English model. Private schools are few in number and inconsiderable in influence.

All state-supported primary and secondary schools in Canada, as well as major higher institutions, are coeducational, except those of the Roman Catholic school system of Quebec. In Australia young boys and girls are taught separately only in the largest primary schools. Some states conduct separate high schools for each sex in the capital cities, largely for the purpose of economy, and most academic high schools are one sex. In New Zealand the public primary schools are mixed, but secondary education is given in both mixed and one-sexed schools. Higher education establishments in Australia and New Zealand are open to women without limitation.

**Continental Europe.**—In western Europe the Scandinavian countries are the extreme exponents of coeducation. Denmark accepted the principle in the 18th century and all its primary and secondary schools are coeducational. In Norway coeducation was adopted by law in 1896; all primary and nearly all secondary schools are coeducational, a few private schools being the only exceptions. Sweden adopted coeducation early in the 20th century and except for a few secondary schools is wholly coeducational. Finland has a rather larger proportion of segregated secondary schools.

In the Netherlands coeducation was permitted in 1871 and by 1886 had become general except in Roman Catholic districts, which still uphold segregation at the secondary stage. In Belgium, on the other hand, two-thirds of the primary schools are single-sex and there are practically no mixed intermediate or secondary schools. In France two-thirds of the 38,000 communes conduct coeducational one-teacher primary schools but larger elementary schools are usually single sex. In Spain the primary schools are mixed but the intermediate and secondary schools are not. In Portugal there are separate primary schools for boys and girls and at the secondary level sexes are taught separately in the main towns but together in the provincial ones. In Switzerland mixed elementary and secondary schools are general, although some cantons maintain separate schools at both levels. The elementary and secondary schools of Italy are coeducational. In Greece the primary and about half of the secondary schools are mixed.

Until the closing decades of the 19th century it was practically impossible for a German girl to get secondary education, and when girls' secondary schools were introduced they were of inferior status to boys'. Hitler increased this inferiority by excluding girls from *Gymnasium* courses. After World War II some *Länder* made coeducation their objective, but the tradition of segregation dies hard and in the Federal Republic of Germany the teaching of boys and girls separately has been the general tradition in primary schools, although coeducation has been the practice in small rural schools. Also, in a number of large municipalities, such as Bremen, Hamburg and West Berlin, coeducation at the primary level is now the rule. Coeducation has made little progress at the secondary level.

**U.S.S.R.**—In tsarist Russia boys and girls generally were taught separately, at least in cities, but with the establishment of the U.S.S.R. coeducation became the universal practice. In 1943, however, a decree of the central government called for the abolition of coeducation so that schools might "adapt themselves to the special characteristics of boys and girls." In actual practice the majority of schools continued to operate on a coeducational basis. After prolonged public discussion, in which it was claimed that discipline had deteriorated in boys' schools, that in some girls' schools pupils had been discouraged from interest in science, agriculture, economics and industry, and that segregation was estranging boys and girls, in 1954 coeducation was restored for the "uncomplicated and comradely relations between boys and

girls." In communist East Germany, Czechoslovakia, Poland and Rumania and in Yugoslavia the schools also are coeducational.

**Asia and Africa.**—For many centuries in the orient the belief prevailed that for a woman to assume her proper role in society—that of mother and wife—she required little in the way of schooling. Opportunity for formal education was practically nonexistent for women until about the middle of the 19th century, when Christian missionaries established schools for girls. A trend toward the joint education of the sexes in China had its beginnings in the 1920s, in the early years of the national government, when the meagre opportunities for primary education which existed were opened to boys and girls alike. Joint secondary schools for boys and girls became customary and universities were opened to women. Since the establishment of the communist regime in mainland China in 1949, coeducation has become the rule both in theory and practice at all levels.

In 1872 Japan established a nationwide system of public education and national laws provided for separate schools for the sexes. Coeducation was practised at first only in the primary grades. It was not until 1920 that government universities began to admit women students. The number of women students entering the government universities was limited because no provisions were made to allow girls to enroll in secondary schools of the college preparatory type. The curriculum for Japanese girls was different from that of boys from the third year of elementary school and girls were almost completely prevented from going beyond the primary school, although a few of them attended higher normal schools or private colleges. This attitude was greatly modified during the period of U.S. occupation after World War II when the Japanese adopted the principle of coeducation at all levels and the formerly distinct curricula of the secondary schools were merged. By 1949, 55% of the upper secondary schools were coeducational and the percentage continued to rise. Almost 200 of the private universities became coeducational by the second half of the 20th century.

Since World War II, the United Nations and the United Nations Educational, Scientific and Cultural organization (UNESCO) have provided information about coeducation for nonindustrial countries which shows that the practice of coeducation has gained wide acceptance in the nonwestern world. Except in Muslim societies, elementary schools are partly or wholly mixed almost everywhere and secondary and higher schools are generally conducted for men and women studying together.

In India, where the general practice is to maintain mixed schools for boys and girls at the elementary level and separate ones at the secondary, the second five-year plan provided that education was to be made available to 60% of the children from 6 to 11 years of age who should be educated together so far as might be feasible for the sake of economy. The 1959 "Report of the Commission on National Education" for Pakistan also proposed an expansion of educational facilities, but the equal facilities planned for girls were to be separate in both elementary and secondary schools. The ministries of such Asian nations as Cambodia, Ceylon and Vietnam report that coeducation is seldom practised in the elementary and secondary schools of their countries.

In countries of the middle east, such as Jordan, Saudi Arabia, Egypt, Iraq and Iran, there are virtually no mixed schools. Turkey, however, utilizes coeducation in all primary schools, and Israel, at all levels. The announced policy in Egypt is to encourage coeducation at the primary level.

In Africa the practice regarding coeducation varies greatly. In the former French territories, including Malagasy Republic, in Kenya and in Ghana the elementary schools are mixed. In Ethiopia and in the Republic of the Congo (former Belgian Congo) separate primary schools for boys and girls have been the rule. In Togo larger towns have mixed and the smaller ones separate schools.

In many nonindustrial nations, where coeducation has been adopted at the secondary level, the legal fact of coeducation does not mean that there is equal access to schools. In Nepal only 3% of the pupils in the secondary schools are girls. Failure to implement policies favouring coeducation in African and Asian terri-

tories is due to religious scruples, in part, and to the facts that parents are unwilling to send female children to schools taught by men, that the work of girls is needed and that boys are accorded priority. Sometimes initiation ceremonies and the custom of early marriage work against the adoption of coeducation in practice.

**Latin America.**—Latin-American countries are alike in rejecting coeducation at primary and secondary levels and in accepting it in higher learning institutions. Two factors have militated against coeducation at the lower levels over most of Latin America: (1) industrialization, which intensifies the need for coeducation, is relatively recent even in the most developed countries; and (2) Roman Catholic tradition, speaking broadly, is opposed to coeducation, particularly for adolescents. Peru, however, reports that 27% of its primary schools are coeducational. Costa Rica and the Dominican Republic report that whether schools are mixed depends on the size of the towns in which they are located, and in Bolivia, Brazil, Chile and Uruguay most of the rural schools are coeducational, although when circumstances permit separate schools are preferred.

(C. A. Eo.)

**COEFFICIENT.** This term was introduced into algebra by François Vieta at the close of the 16th century to denote either of the two rational factors of a monomial. Thus in the expression  $ab$ , either  $a$  or  $b$  is the coefficient of the other. In the case of a product of a constant by a variable, it is usual to call the constant factor the coefficient. Thus the numbers 2,  $-1$ , 0, and  $a$  are the coefficients of the polynomial  $2x^3 - x^2 + a$ .

The integer  $\binom{n}{r} = \frac{n!}{r!(n-r)!}$  is the coefficient of the term  $x^r y^{n-r}$  in the expansion of  $(x+y)^n$  by the binomial theorem. Such integers are called binomial coefficients.

If  $z=f(x,y)$ , then  $dz = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy$  so that the partial derivatives  $\partial f/\partial x$  and  $\partial f/\partial y$  are often called differential coefficients.

In physics and mechanics, the term "coefficient" is applied to a number of constants that have to be determined experimentally. Thus if  $F$  is the force due to friction between two surfaces, and if  $N$  is the normal pressure between the surfaces, then  $F=\mu N$  where  $\mu$  is a constant depending on the condition and nature of the surfaces in contact, called the coefficient of friction.

A body normally expands when heated, and the change in length of a bar of unit length per degree change in temperature is a constant, called the coefficient of linear expansion of the substance. The coefficient of pressure of a gas is the ratio of the change in pressure per degree to the pressure at the ice point, the volume remaining constant.

In the division of one polynomial by another, the method of detached coefficients may be used. When the divisor is of the form  $x-c$ , the method is particularly simple, and is known as synthetic division. Let it be required to divide  $3x^4 - 8x^3 - 2x + 5$  by  $x-3$ . The coefficients of the dividend are written down in order, 0's being supplied if not all powers of  $x$  are present. The first coefficient is brought down unchanged. This is multiplied by

3 and added to the next coefficient. The sum 1 is multiplied by 3 and added to the next coefficient, etc. The partial quotient is

$$\begin{array}{r|l} 3 & -8 & 0 & -2 & 5 & \\ \hline & 9 & 3 & 9 & 21 & \\ \hline 3 & 1 & 3 & 7 & 26 & \end{array} \quad \begin{array}{l} \\ \\ 3 \end{array}$$

$3x^3 + x^2 + 3x + 7$  with the remainder 26. See ALGEBRA; POLYNOMIAL.

**COELHOORN, MENNO**, BARON VAN (1641–1704), Dutch soldier and military engineer distinguished as a master of siege warfare, was born at Lettinga-State, Friesland, in March 1641, the son of an infantry officer. A captain at 26, he was wounded at the capture of Maastricht by the French (June 1673). His abilities were first apparent in 1674 at the siege of Grave, when he used to great effect a new type of mortar of his own design. His first book on siege techniques, *Verhandeling over de versterckinge des vyfhoek met alle syne buytenwerken*, appeared in 1682. The most important of his numerous works, the *Nieuwe Vestingbouw* (1685) was translated into German, French, English and Russian. Coehoorn perfected a system of fortification adapted to level ground, such as in the Netherlands. Also, he advocated a new strategy for the defense of citadels, involving the active deployment of troops instead of relying only on moats and ramparts.

In 1689 Coehoorn greatly assisted Frederick III of Brandenburg at the capture of Bonn, and in 1690 he served as a brigadier at the unsuccessful defense of Fleurus against the French. He was next put in charge of the defense of Namur, whose fortifications he had improved. Nevertheless, in June 1692, Namur fell to the French, and only in 1695 was Coehoorn able to regain it. In this same year he was appointed lieutenant general of the infantry and engineer-general of the fortifications and, in 1697, master general of the artillery. In his new capacities he fortified Groningen, Zwolle, Nijmegen, Breda and Bergen op Zoom. Coehoorn took an active part in the early years of the War of the Spanish Succession, but died of an apoplexy at The Hague on March 17, 1704.

See G. T. van Coehoorn (Menno's son), *Het leven van Menno Baron van Coehoorn*, ed. by J. W. Sypestein (1860). (E. H. K.)

**COELACANTH.** Coelacanths are fish of the order Coelacanthini, members of which appeared about 350,000,000 years ago and spread over much of the world, leaving numerous fossil remains which apparently ceased 60,000,000 years ago. It was therefore startling when the first living coelacanth (*Latimeria chalumnae*) was trawled in 40 fathoms near East London, U. of S. Af., in 1938. The second was caught by a native on a line in about 40 fathoms near the Comoro Islands in Dec. 1952. This, *Malania anjouanae*, a male, lacked a first dorsal and extra tail but was probably mutilated in early life. So little was known about coelacanths that it was believed further specimens might show the two to be male and female of the same species. The sex of *Latimeria* was unknown as the soft parts were lost.

Modern coelacanths are bigger than most fossil forms. *Latimeria* was 60 in. long and weighed 127 lb., *Malania* 54 in. and 87 lb. In 1953 and 1954 five more coelacanths were captured and preserved at the Comoros, establishing this as their home.

Coelacanths are grouped in four families, three extinct and one existing, Latimeriidae. These fall in the superorder Crossopterygii (fringe-finned), the early forms of whose two related orders,

Coelacanthini and Rhipidistia, lived in swamps and probably crawled out of the water at intervals. Rhipidistian descendants colonized the land (some investigators believe that these forms gave rise to the amphibians), but coelacanths remained aquatic, some probably always marine, leaving no fossil remains. Being close links with the remote past, they may shed light on earlier life.

Almost unchanged in form since their origin, coelacanths have characteristic limblike fins, probably still used today for crawling about in the sea. The tail is large, symmetrical and in most fossil and one recent form there is a small extra tail behind. The skeleton is mostly cartilage, but part of the skull and the basal plates of the fins in the body are bony. The powerful mouth differs from that of most fishes, lacking the "maxillary" bones in the upper jaw. The gill arches are bony, with strong teeth above. Even early coelacanths had scales overlapping like those of modern fishes, with a lateral line.

Coelacanths are robust and powerful flesh eaters, almost certainly dwellers among reefs, where they pounce on prey. The intestines are short and include a spiral valve. Inside *Malania* were the eyeballs of a fish of at least 15 lb. weight. (J. L. B. S.)

**COELENTERATA**, the phylum of animals that includes such forms as medusae (jellyfish), sea anemones, corals, marine hydroids, fresh-water hydras, sea fans and the Portuguese man-of-war. The name Coelenterata, derived from the Greek meaning hollow-gut, is descriptive of the general organization of the body around the hollow gut or coelenteron. Another name, Cnidaria,

COELACANTH (LATIMERIA)

girls." In communist East Germany, Czechoslovakia, Poland and Rumania and in Yugoslavia the schools also are coeducational.

**Asia and Africa.**—For many centuries in the orient the belief prevailed that for a woman to assume her proper role in society—that of mother and wife—she required little in the way of schooling. Opportunity for formal education was practically nonexistent for women until about the middle of the 19th century, when Christian missionaries established schools for girls. A trend toward the joint education of the sexes in China had its beginnings in the 1920s, in the early years of the national government, when the meagre opportunities for primary education which existed were opened to boys and girls alike. Joint secondary schools for boys and girls became customary and universities were opened to women. Since the establishment of the communist regime in mainland China in 1949, coeducation has become the rule both in theory and practice at all levels.

In 1872 Japan established a nationwide system of public education and national laws provided for separate schools for the sexes. Coeducation was practised at first only in the primary grades. It was not until 1920 that government universities began to admit women students. The number of women students entering the government universities was limited because no provisions were made to allow girls to enroll in secondary schools of the college preparatory type. The curriculum for Japanese girls was different from that of boys from the third year of elementary school and girls were almost completely prevented from going beyond the primary school, although a few of them attended higher normal schools or private colleges. This attitude was greatly modified during the period of U.S. occupation after World War II when the Japanese adopted the principle of coeducation at all levels and the formerly distinct curricula of the secondary schools were merged. By 1949, 55% of the upper secondary schools were coeducational and the percentage continued to rise. Almost 200 of the private universities became coeducational by the second half of the 20th century.

Since World War II, the United Nations and the United Nations Educational, Scientific and Cultural organization (UNESCO) have provided information about coeducation for nonindustrial countries which shows that the practice of coeducation has gained wide acceptance in the nonwestern world. Except in Muslim societies, elementary schools are partly or wholly mixed almost everywhere and secondary and higher schools are generally conducted for men and women studying together.

In India, where the general practice is to maintain mixed schools for boys and girls at the elementary level and separate ones at the secondary, the second five-year plan provided that education was to be made available to 60% of the children from 6 to 11 years of age who should be educated together so far as might be feasible for the sake of economy. The 1959 "Report of the Commission on National Education" for Pakistan also proposed an expansion of educational facilities, but the equal facilities planned for girls were to be separate in both elementary and secondary schools. The ministries of such Asian nations as Cambodia, Ceylon and Vietnam report that coeducation is seldom practised in the elementary and secondary schools of their countries.

In countries of the middle east, such as Jordan, Saudi Arabia, Egypt, Iraq and Iran, there are virtually no mixed schools. Turkey, however, utilizes coeducation in all primary schools, and Israel, at all levels. The announced policy in Egypt is to encourage coeducation at the primary level.

In Africa the practice regarding coeducation varies greatly. In the former French territories, including Malagasy Republic, in Kenya and in Ghana the elementary schools are mixed. In Ethiopia and in the Republic of the Congo (former Belgian Congo) separate primary schools for boys and girls have been the rule. In Togo larger towns have mixed and the smaller ones separate schools.

In many nonindustrial nations, where coeducation has been adopted at the secondary level, the legal fact of coeducation does not mean that there is equal access to schools. In Nepal only 3% of the pupils in the secondary schools are girls. Failure to implement policies favouring coeducation in African and Asian terri-

tories is due to religious scruples, in part, and to the facts that parents are unwilling to send female children to schools taught by men, that the work of girls is needed and that boys are accorded priority. Sometimes initiation ceremonies and the custom of early marriage work against the adoption of coeducation in practice.

**Latin America.**—Latin-American countries are alike in rejecting coeducation at primary and secondary levels and in accepting it in higher learning institutions. Two factors have militated against coeducation at the lower levels over most of Latin America: (1) industrialization, which intensifies the need for coeducation, is relatively recent even in the most developed countries; and (2) Roman Catholic tradition, speaking broadly, is opposed to coeducation, particularly for adolescents. Peru, however, reports that 27% of its primary schools are coeducational. Costa Rica and the Dominican Republic report that whether schools are mixed depends on the size of the towns in which they are located, and in Bolivia, Brazil, Chile and Uruguay most of the rural schools are coeducational, although when circumstances permit separate schools are preferred.

bell. Hanging down inside the bell, from its midpoint, is a tubular structure, the manubrium, that carries the mouth at its free end. The tentacles of the medusa are located at the margin of the bell. (See JELLYFISH.)

**Alternation of Generations.**—One of the striking features of the Coelenterata is that within the life history of a single individual both the polyp and medusa may occur.

In many coelenterates of the classes Hydrozoa and Scyphozoa, sexual reproduction leads to the development of a larval stage (fig. 3), the planula (see *Reproduction and Development*), which later attaches and develops into a polyp. This polyp may remain single or, by asexually reproducing itself, may become colonial. The polypoid phase may be regarded as a juvenile stage, specialized to live an attached life. Later, by asexual means, the polyp buds off free-swimming medusae that become the sexually adult forms of the species. Alternation of generations, therefore, as it is used here, refers to the alternation, within the life history of a species, of an asexually reproductive stage, the polyp, with a sexually reproductive stage, the medusa.

**Colonies and Polymorphism.**—No colonial medusae are known, but colonies of polyps occur in all classes of Coelenterata. In all cases colony formation is the product of asexual reproduction by the polyp. Secondary individuals are formed as buds from

AFTER CARL GREN & GEMMILL, FROM STEPHENSON, "THE BRITISH SEA ANEMONES"; BY COURTESY OF THE RAY SOCIETY, WITH AN ADDITION

FIG. 3.—COELENTERATE DEVELOPMENT

the base or sides of existing polyps, or from the ends of stolons sent out by polyps. In most colonies the body cavities of the several constituent polyps are connected by tubular passages, so that food obtained by one individual may serve as nourishment for all.

The existence within a species of several types of individuals is cited as an example of polymorphism. Not uncommonly various polyps in a colony become specialized for some particular function. For example, in certain hydrozoan colonies one can identify polyps specialized for protection, feeding and reproduction. The medusae produced by some hydrozoan colonies can be looked upon as specializations for sexual reproduction and locomotion.

**Food and Feeding.**—The coelenterates are primarily carnivores that depend on stinging capsules called nematocysts (see below) to sting and subdue (by paralysis) prey such as marine worms, other coelenterates, larval animals of many different sorts and small fishes. However, some coelenterates, such as certain scyphozoan jellyfish and some corals, do not seem to use nematocysts for food gathering; instead, they collect minute organisms and organic debris by means of ciliary-mucous mechanisms. Small particles entrapped in mucus are carried to the mouth by ciliary currents, sometimes aided by movements of the tentacles.

Food is ingested in the following manner. The tentacles carry the food toward the mouth, and the latter in some cases rises to receive it. The mouth then opens and the oral lips grasp the food. Swallowing is accomplished by muscular action alone or by a combination of muscular and ciliary movements. Many polypoid coelenterates can ingest prey as big as themselves, or even bigger (fig. 4).

A long argument has been carried out in the literature dealing with the nutrition and feeding of reef-forming corals and other coelenterates that possess masses of unicellular algae in their gastrodermal cells. One school of thought maintained that reef-corals are restricted to shallow, well illuminated waters that are poor in food for corals and that the algae in the animals' tissues serves as food.

An opposing view maintained that corals feed exclusively on animal matter and that they cannot digest algal cells. In furtherance of the latter view it has also been shown that corals (with algal symbionts) that normally grow in light can grow and be kept healthy for at least six months in the dark. The argument seemed stalemated until it was shown, by using radioactive labeled carbon compounds, that the algal cells gave off, as byproducts of photosynthesis, organic substances that subsequently diffuse into the tissues of the host coelenterate. The degree to which corals or other coelenterates are actually dependent upon their algal symbionts has not yet been established.

**Coelenterates and Other Animals.**—Coelenterates are related to other animals in a wide variety of ways. One can generalize that coelenterates are predaceous carnivores that may be placed close to the top of ecological food chains.

Intimate associations of coelenterates with a number of animals are well known. For example, small fish are common companions of many large jellyfish and the Portuguese man-of-war. These fish find protection from possible predators among the tentacles of their hosts, and they seem not to cause discharge of the hosts' nematocysts. However, if such a fish is injured, its exposed tissue does cause nematocyst discharge, and the fish becomes a prey of its host.

Fish also live intimately with a number of large sea anemones, and their relationships seem to be the same as those that live with jellyfish. Some anemones are known that live only on the shells occupied by hermit crabs; others live only on the stalks of sponges or the branches of sea fans.

A number of hydroids are known that have close associations with such diverse hosts as fish, worms and clams. In most instances the hydroids have become adapted to living on some part of the host without doing harm to the host. Such relationships may be described as commensal. A few hydroids, such as *Hydrichthys* on several species of fish and *Polypodium* in the ovarian eggs of the sturgeon, seem to be true parasites.

FIG. 4.—HYDRA INGESTING WATER FLEA (DAPHNIA)

(Left) Hydra tentacles carry the prey toward the mouth as the latter rises to receive it; (left centre) digestion begins as the prey passes down into the body cavity; (right centre) tentacles and body cavity contract as digestion proceeds; (right) digestion almost completed, the hydra extends its tentacles to await new prey

### FORM AND FUNCTION

**Structure of a Coelenterate.**—The body of a coelenterate may be analogized to a sac with a single opening. This opening is the mouth or stomodaeum, which serves both for the ingestion of food and the egestion of undigestible substances. The mouth is surrounded at a greater or lesser distance by tentacles that are used in food gathering and in defense against other organisms. Both the food gathering and defensive qualities of these tentacles are aided by the possession of nematocysts.

The outer surfaces of the body are covered by a single tissue layer, the epidermis or ectoderm. This tissue layer possesses cells of many types (fig. 5), notably those which form nematocysts (cnidoblasts), sensory cells, nervous cells (neurons), glandular cells, undifferentiated interstitial cells and epidermal cells. Epidermal cells may possess cilia and may have their bases specialized as contractile or muscular structures.

The inner surfaces of the body are likewise covered by a single tissue layer, the gastrodermis or endoderm. Here again essentially the same cell types will be found. The gastrodermis is specialized as a digestive layer. Food material that enters the coelenteron is soon broken down to a particulate mass as a result of the action of strong protein-splitting enzymes released by the gastrodermis. The particulate material is then ingested by the cells lining the coelenteron. It is within these cells that final digestion occurs. The useful products of digestion either are diffused throughout the organism or are carried by wandering cells (amoebocytes).

The coelenteron may be a simple sac or one complexly subdivided by partitions and canal systems.

A third body layer, the mesogloea, occurs between the epidermis and gastrodermis. This layer may be so thin as to be nearly indistinguishable or very thick, with many cells and fibres as well as large quantities of a gelatinous ground substance. The mesogloea, when well developed as in jellyfish, serves as an internal elastic skeleton against which muscles may work. In many polyps, on the other hand, the thin mesogloea seems to be little more than a cementing layer between the epidermis and gastrodermis.

**Muscles and Motion.**—In the morphologically simplest coelenterates, such as hydrozoan polyps, there are no discrete muscles, or even muscle cells. Instead there are found in the epidermis and gastrodermis certain epithelial cells, better described as musculoepithelial cells. The muscular, basal portion of these cells is attached to the mesogloea. In the epidermis of the polyp these cells have their muscular bases arranged longitudinally, whereas, in the gastrodermis their bases are arranged transversely in a circular sheath that limits the coelenteron. Elongation is accomplished by constriction of the circular muscles, and shorten-

ing or bending by contraction of the longitudinal muscles.

In larger and more complex polyps, such as sea anemones, discrete muscle cells are not found, but special areas of the epithelium are set aside as primarily muscular in function. The longitudinal, external muscle layer is largely lost, being replaced by longitudinal muscles running along the faces of the mesenteries that subdivide the coelenteron. The mesogloea of these polyps is in general more elastic and thicker than that of smaller polyps, and the coelenteron is larger and contains more water. The contained water may be regarded as a "hydraulic skeleton" against which the muscles act. Even though special muscles are present, they are still maintained as a single layer. Space is provided for an increased number of units by a folding of the mesogloea rather than a piling up in layers of muscle cells.

In medusae the muscles are represented by epithelial cells on the concave inner or subumbrellar surface only. They are arranged in circular and radial groups, and their contractions cause the pulsing movements of the bell. These muscles act entirely against the gelatinous, much thickened elastic mesogloea. Medusae swim by forcing or jetting the subumbrellar water out of the bell. After each contraction the elasticity of the mesogloea returns the bell to the normal resting shape.

The movements of most coelenterates are restricted to extensions, contractions and bendings of the tentacles and body. Medu-

sae, as noted above, are free-swimming, and two anemones also are known to swim. Swimming in anemones, however, is restricted to writhing movements of the column and undulating and flapping movements of the oral disc and tentacles. Some hydrozoans occur as free-floating individuals or colonies. One group of colonial hydroids, the Siphonophora, have attached medusae in their colonies and use them as locomotory structures. Some polyps are capable of a limited creeping by means of the ameiboid movement of cells on the attachment disc; a few move by a more rapid "somersaulting," end-for-end (fig. 6).

**Skeletal Structures.**—Two functionally different sorts of skeletal systems occur in coelenterates. The first type, already referred to, is of an internal nature and is either the mesogloea or the "hydraulic skeleton" described for most polyps. Of a different sort are the exoskeletons.

In most hydrozoan polyps, and in a few scyphozoans, there is a tubular, external, secreted sheath, more or less completely encompassing the whole individual or colony. Such skeletons are flexible enough to allow bending but rigid enough to support large colonies in an upright position. In a group of hydrozoans called hydrocorals, and in the true corals, there is an exoskeleton of limestone; the polyps live in cups on the surface of such skeletons. A few hydroids and a number of anthozoans have small calcareous spicules that aid in the support of the polyps.

Still another, and different, skeleton is found in sea fans and sea pens: an axial, tough, but flexible, skeleton upon which the fleshy colony of polyps grows. An interesting modification of the skeleton to form a float from which the colony hangs is found in such coelenterates as the hydroid *Velella* and the Portuguese man-of-war.

Perhaps the most phenomenal matter relating to skeletons is the way in which for eons the skeletons of corals have accumulated to form islands and reefs such as the atolls of the Pacific and the Great Barrier Reef of Australia. (See ANTHOZOA; CORAL; CORAL REEF.)

**Respiration, Circulation and Excretion.**—These functions generally are carried out without benefit of special structures. Respiration and excretion occur through simple diffusion, a direct exchange between the tissue and the external environment or the water contained in the coelenteron. Circulation is perhaps aided by the movements of fluids in the coelenteron due to cilia and muscular movements of the body. A few coelenterate polyps, notably some anemones, have curious systems of channels in the body wall which may aid in circulation. Medusae typically have the coelenteron divided into canals that act as distributional structures. There is no vascular system or blood in the usual sense of these words.

**Nervous System.**—The nervous system of coelenterates has been called primitive because in most parts of the system there are no definable nerves. Furthermore, the direction in which a nervous impulse travels is unregulated; that is, the system is unpolarized. It consists of identifiable neurons, frequently of a multipolar type (fig. 7), which are organized into one or two networks. In polyps in general there seems to be a single nerve net. Medusae, on the other hand, seem to have two networks, one related to swimming movements and one to other movements. Various sensory structures such as light-sensitive ocelli and balance organs (statocysts) are present in medusae, but not in polyps, and are richly supplied with nervous tissue. Nerve-like aggregations occur as rings round the margins of some medusae. From the point of input, a stimulus usually spreads nervous impulses in all directions from its origin, and commonly the distance of

spread is related to the frequency of repetition of the stimulus. Thus a single stimulus may have little or no visible effect, but a repetition of this stimulus may intensify the impulses, spreading them for some distance or even throughout the whole nervous system. This phenomenon is called facilitation.

In some colonial coelenterates there may be no interconnections of the nervous systems of the constituent polyps; in others there may be well-developed interconnections. The nervous system is most richly represented by a subepidermal plexus of neurons, although in some forms there is a subgastrodermal net as well. No connections of the inner and outer net, other than in the region of the stomodaeum, are known.

**Nematocysts.**—These minute (5–100 microns) and intracellular capsules function in food gathering, adhesion to foreign objects and protection. They are one of the main reasons for the success that the coelenterates have attained as a group. There are about 20 morphologically distinct types of nematocysts, some of which

are illustrated in fig. 8. Nematocysts are formed in special cells called cnidoblasts; these nematocyst-forming cells may move some distance through the tissues before reaching their final location.

Nematocysts have double walled capsules that contain a hollow, usually spined thread. Before the nematocyst is triggered off the thread is inside out, with the spines facing the central hollow of the tube. On contact with foreign objects, the nematocyst "explodes." A lid, which is usually present, pops aside, and the contained thread everts with a twisting motion. As eversion proceeds, the spines act like a drill tip, penetrating and pulling the thread into the foreign object. Poisons, which act as paralytic agents, are contained in the nematocyst and pass outward through the hollow thread into the foreign object. There is an active uptake of water and a shrinkage of the capsule when a nematocyst explodes. The precise forces involved are not well understood. Nematocysts are not under nervous control. Experimentally, they will not explode on contact with clean, chemically inert objects. However, contact is required for explosion in the natural situation.

FIG. 7.—COELENTERATE NERVOUS SYSTEMS

(A) Nervous tissue of an anemone, showing the epidermal ganglion-cell layer from the oral disc as seen from the inner surface of the epidermis (microscopic view); (B) nervous system of hydra (enlarged); (C) ring arrangement of epidermal nerve cells in the pedal disc of hydra (microscopic view)

Some nematocysts do not possess spines and are adhesive in function, whereas other spineless types act as lassos and entangle setae and bristles of small prey (fig. 9). Once a nematocyst has exploded it soon pulls free from the surrounding cell and is discarded. Nematocysts that penetrate prey help to hold the object and also cause paralysis of the prey. After ingestion the prey may be further stung by nematocysts in the coelenteron.

The toxin in nematocysts has not been positively identified. For man a sting by a Portuguese man-of-war or many other coelenterates such as large medusae or stinging corals is very painful and may cause temporary paralysis or even anaphylactic shock and death in an extreme case.

## REPRODUCTION AND DEVELOPMENT

All known coelenterates reproduce sexually at some stage in their lives. The sexes are usually found in separate individuals, and although hermaphroditism is not unknown, it is rare. Most commonly, eggs and sperm are released to the external environ-

ment, where fertilization occurs. However, in some hydroids, medusae and anthozoans fertilization occurs at the point where the eggs are produced and the developmental stages occur in the parent organism.

The details of development of an anemone to the larval stage, the *planula*, are illustrated in fig. 3. Perhaps more typically the gastrula is solid rather than hollow, and the mode of development of the gastrula from the hollow blastula is highly variable. The planula larva, with its heavy coat of cilia, is free-swimming as a rule. The planula of an animal having a polypoid phase eventually attaches by the anterior or forward-moving end. The anterior end gives rise to the base and the attachment structures of the polyp, while the posterior end gives rise to the mouth and tentacles. The planula of a medusa that has no true polypoid stage commonly will sprout tentacles at about its midpoint. Such a stage is somewhat polyplike and is known as an actinula. The posterior end of the actinula will become the manubrium, bearing the mouth, and the aboral half of the actinula will grow into the bell of the medusa.

## RELATIONSHIPS AND EVOLUTION

**Relationships Among Coelenterates.**—Among themselves, the three classes of coelenterates—Hydrozoa, Scyphozoa and Anthozoa—seem closely related. The Hydrozoa are at once the morphologically simplest but, at the same time, the most diverse. Their simplicity suggests that they may be the ancestral coelenterates, while their diversity suggests a highly advanced group.

The Scyphozoa seem intermediate between the Hydrozoa and Anthozoa. Their medusae are like those of the Hydrozoa, whereas their internal complexity suggests affinities to the Anthozoa. Various schemes of evolution have been suggested that have placed either the Hydrozoa or Anthozoa at the stem of the group. The fossil record offers little help in resolving the question.

**Evolutionary Ancestry.**—The relationships of Coelenterata to other phyla of animals is not clear. Suggestions have been made that the coelenterates represent an evolution from colonial protozoans, on the one hand, and from early flatwormlike ancestors, on the other. There is very little evidence to support either of these views.

If one accepts a protozoan ancestry, one can look to the coelenterates as organisms of early metazoan vintage. Only two well-developed cell layers are present in many coelenterates; these layers may be analogized and homologized with the developing ectoderm and endoderm of more highly evolved groups. On theoretical grounds the organization of the coelenterate body can be compared to the developmental stage called gastrula.

Those people who support the theory that coelenterates are derived from early flatworms consider the somewhat obscured bilateral symmetry of the Anthozoa as a point of evidence. The claim is then made that with the development of a sessile way of life the inherent bilaterality evolved toward the radial. (As a point of interest, this same line of argument is well accepted as part of the interpretation of echinoderm ancestry from bilateral ances-

tral forms.) The nematocysts of coelenterates may be compared to such intracellular structures as the rhabdites of flatworms. There is no embryological evidence to support the view that either protozoans or flatworms are ancestral to coelenterates. Against the hypothesis of flatworm ancestry: the coelenterates, which possess the best developed mesogloea (possible mesoderm or third tissue layer), develop this tissue from ectodermal rather than endodermal tissue as do the flatworms.

In view of the present state of knowledge of coelenterate phylogeny, it seems best not to accept any particular group as ancestral to the coelenterates and to leave to further inquiry the question of whether polyp, medusa or planula represent the ancestral coelenterate.

## CLASSIFICATION

The coelenterates are divided into three major groups or classes, based in part on the complexity of the coelenteron, as follows:

**Class Hydrozoa.**—This group includes marine hydroids, hydro-medusae (hydrozoan jellyfish), fresh-water hydras (fig. 4) and the Portuguese man-of-war. As stated earlier the Hydrozoa are morphologically the simplest of all coelenterates. They are marine organisms except for the hydras and a fresh-water jellyfish, *Craspedacusta*. The coelenteron of the Hydrozoa, a simple cavity without compartments or nematocysts, may extend into the tentacles. In the hydrozoan jellyfish the coelenteron becomes ramified into four or more canals that radiate from a central stomach. A ring canal usually courses round the margin of the bell and unites the radial canals. Hydrozoan jellyfish possess a diaphragm-like structure, the velum, which reduces the size of the subumbrellar opening. In some Hydrozoa the hydroid is the sexually mature form; in others the hydroid is only a juvenile stage, budding off jellyfish that become the sexually mature stage. Some hydrozoan jellyfish, however, have no hydroid stage. Many colonial marine hydroids are polymorphic. (See HYDROZOA.)

**Class Scyphozoa.**—These are large jellyfish common in shallow waters of all oceans and seas of the world, although one group (the Coronatae) occurs in deep waters. There are no fresh-water

Scyphozoa. The coelenteron is divided into four chambers by inward projections of the body wall. Commonly there are small groups of internal (gastric) tentacles on the sides of these projections. The coelenteron possesses nematocysts. A characteristic feature of the scyphozoan jellyfish is the possession of eight (rarely four) or more complex marginal sensory structures called rhopalia. No velum is present, and the bell margin is usually scalloped. A complex system of radial canals runs from each of the stomach pouches out to the margin of the bell, where they are joined by a ring canal. The radial canals usually are much branched and commonly join one another in a network.

Almost all scyphozoans are free-swimming, or at least are capable of free movement. Only one

group (the Stauromedusae or Lacerariidae) live as attached polyplike animals. The life history of many of the Scyphozoa involves a polypoid juvenile stage, a scyphistoma, that buds off the adult form.

**Class Anthozoa.**—This group includes sea anemones, true corals, sea fans, sea feathers, sea

pansies and soft corals. They are all polypoid animals, occurring on and in the bottom in all marine habitats from shallow waters to the greatest depths. The coelenteron bears nematocysts and is compartmented into six, eight or more divisions by mesenteries arranged radially or radiobilaterally round the coelenteron. Anthozoans are generally characterized by their sessility, locomotion usually being limited to a very slow creeping by means of a pedal disc. However, one species of anemone is planktonic and at least two anemones are capable of limited, undirected, swimming movements. The great majority of anthozoans are free-swimming only during their larval stages. Many anthozoans form colonial masses composed of similar individuals budded from an original sexually produced polyp. Some colonies exhibit polymorphism among the members. Skeletons of lime characterize the corals, whereas other anthozoans, such as sea fans, produce tough but flexible proteinaceous skeletons. (See ANTHOZOA.)

**COELHO, JOSÉ FRANCISCO TRINDADE** (1861-1908), Portuguese writer, best known for his short stories, was born in Mogadouro in the Trás os Montes region on June 18, 1861. He entered the University of Coimbra but, unexpectedly, failed his first-year examination. Nevertheless, Coelho remained at the university, paying his way by taking private pupils and writing for various newspapers. He graduated in 1885 and then entered the government's legal service, but also continued with his journalistic work and his own writing. He retired from the legal service in 1907 and committed suicide on June 9, 1908. It is on the stories published under the title *Os Meus Amores* (1891; enlarged 3rd ed., 1901) that his fame rests. Of unequal merit, they have a rural setting, and the characters are drawn almost exclusively from a simple, primitive world. Coelho is less successful in the contriving of a satisfactory plot than in the description of natural scenery and the evocation of his own childhood experiences. Besides some writings on legal topics, he produced a volume of memoirs of his student days in Coimbra, *In Illo Tempore* (1902).

See F. Ramos, *Trindade Coelho, homem de letras* (1947); B. da Fonseca, "Trindade Coelho," in *Perspectiva da Literatura Portuguesa do Século XIX*, vol. II (1948). (N. J. L.)

**COELLO, ALONSO SÁNCHEZ:** see SÁNCHEZ COELLO, ALONSO.

**COELLO, CLAUDIO** (c. 1635-1693), Spanish painter, the last important master of the great Madrid school of the 17th century, was born at Madrid, son of Faustino Coelho, a well-known Portuguese worker in bronze. He studied under Francisco Rizi, and was dominated at first by an overcharged, exaggerated style, which was then beginning to be admired in Madrid. He then studied works in the royal collections, to which he secured access through his friendship with the court painter Juan Car-

reño. He also profited by his friendship with Josef Donoso, from whom he probably learned fresco painting, and with whom he co-operated in the painting of frescoes in some churches and palaces of Madrid. In 1671 he decorated the ceiling of the vestry in Toledo cathedral. In 1683 he was commissioned by the archbishop of Saragossa to paint frescoes in the cupola and the transept of the Augustine church. On his return to Madrid he became court painter to King Charles II (1684) and undertook the altarpiece for the sacristy in the Escorial, representing the "Transfer of the Holy Eucharist." The scene is represented as taking place in the same room in which the picture is hung. It is a fine arrangement of space in the baroque style containing some 50 portraits including that of Charles II. This work is his masterpiece. It is nearly allied to the art of Velázquez and Carreño, and shows strong colour and fine draftsmanship. He seems to have tried to stem the decadence that was engulfing Spanish art, and his work was greatly admired. Then Luca Giordano arrived in 1692, and, according to tradition, the preference shown by the court to the Italian painter hurt Coello and hastened his death. His last work was the "Martyrdom of St. Stephen," painted for the Dominican church at Salamanca. He died on April 20, 1693, at Madrid, and was buried in the Church of San Andrés.

His works are to be seen in the churches of Madrid and other cities of Spain, at Munich, Budapest, Frankfurt and London.

**COELOM AND SEROUS MEMBRANES** are the body cavity and the membranes that line it. The coelom was originally a space within the body of lower animals in which nitrogenous wastes collected before being voided. When the apparatus for filtering and discharging urinary products was combined and separated from the coelom, this cavity became a huge, fluid-filled bursa which permitted the visceral organs to move about in a nearly frictionless manner when adjusting to movements of the body as a whole. In mammalian anatomy this coelom is divided into a pericardial cavity (containing the heart), two pleural cavities (containing the lungs), a peritoneal cavity (containing the abdominal and pelvic organs) and two vaginal processes (containing the testicles). The lining of the coelomic cavities is known as the tunica serosa, or serous membrane. This layer is also reflected over any organs that protrude into the coelom and is wrapped about those parts that traverse it. In the latter instance it suspends these parts by a system of mesenteries or ligaments. The portion of the serosa that underlies and lines the body wall is called the parietal layer. Portions that serve as mesenteries and reflect over or envelop organs in or near the midplane belong to the visceral layer. In mammals the linings of the several body cavities are named the pericardium, pleurae and peritoneum.

A serous membrane is simple in structure. Its glistening surface is a single layer of flat epithelial cells that have been given the distinctive name of mesothelium. Beneath this superficial sheet of epithelium there is a layer of local connective tissue that varies in thickness regionally and harbours a cell population that is, in most regions, scanty. Among the cells represented are fibre formers, scavengers and fat storers. Still deeper, in locations where the membrane is freely movable, there is a subserous layer of fibrous (and sometimes fatty) tissue that binds the serous membrane to underlying structures. The membrane secretes the watery serous fluid which contains a variety of free cells. The amount of exudate is normally small, but it can increase enormously in diseased conditions. A mesentery results from a folding of a visceral serous membrane about the digestive tube. The greater extents of the two participating membranes fuse by their fibrous components; hence both free surfaces are covered with mesothelium. The omentum of the stomach is the most complicated and physiologically important part of the mesenterial system. In this membrane there are regions beset with innumerable perforations; in certain other areas scavenger cells accumulate along vessels, forming so-called milky spots visible to the naked eye.

**Pericardium.**—The pericardium is a closed sac in the chest that contains the heart. Like all the serous membranes it has a visceral and a parietal layer, the former being closely applied to the heart; to it is due the glossy appearance of a freshly removed heart. The parietal layer is reflected where the great vessels

enter and leave, and there becomes continuous with the visceral layer. Hence everywhere the two layers of the membrane are in contact except for a trace of fluid secreted by the serous walls.

**Pleurae.**—The pleurae, covering the lungs and lining the chest cavity, resemble the pericardium except that the fibrous outer coat of the parietal layer is not nearly so strong. It is closely attached to the inner surface of the chest walls and to the outer layer of the pericardium; above, it is thickened by a fibrous contribution from the scalene muscles and forms the dome of the pleura, which fits into the concavity of the first rib and contains the apex of the lung. The reflection of the serous pleural membrane, from the parietal to the visceral part, takes place at the root of the lung. The upper limit of the pleural cavity reaches about one-half inch above the inner third of the collarbone, while, below, it may be marked out by a line drawn from the 12th thoracic spine to the 10th rib in the midaxillary line, the 8th in the nipple line and the 6th at its junction with the breastbone.

**Peritoneum.**—The peritoneum is a more extensive and complicated membrane. It surrounds the organs of the abdomen and pelvis and, like the other sacs, has a parietal and visceral layer. The line of reflection of these, though continuous, is very tortuous. The peritoneum consists of a greater and lesser sac that communicate through an opening (epiploic foramen, *i.e.*, foramen of Winslow), and the best way of understanding these is to follow the reflections first in a vertical median (sagittal) section and then in a horizontal one.

If a median sagittal section is studied first, and a start made at the umbilicus (*see* fig. 1), the parietal peritoneum is seen to run upward, lining the anterior abdominal wall, and then to pass along the undersurface of the diaphragm until its posterior third is reached. Here there is a reflection onto the liver, forming the anterior layer of the coronary ligament of that organ, while the membrane now becomes visceral and envelops the front of the liver as far back as the transverse fissure on its lower surface. It continues toward the stomach, forming the anterior layer of the lesser omentum, which in this particular region is known as the hepatogastric ligament. It next covers the front of the stomach, and at the lower border runs down as the anterior layer of the lesser omentum, which in this particular region is known as the hepatogastric ligament. It next covers the front of the stomach, and at the lower border runs down as the anterior layer of the lesser omentum, which in this particular region is known as the hepatogastric ligament. It next covers the front of the stomach, and at the lower border runs down as the anterior layer of the lesser omentum, which in this particular region is known as the hepatogastric ligament.

turns up again as the posterior or fourth layer of the greater omentum until the transverse colon is reached, the posterior surface of which it covers and is reflected, as the posterior layer of the transverse mesocolon, to the lower part of the pancreas. After this it turns down and covers the anterior surface of the third part of the duodenum until it reaches the posterior wall of the abdomen, from which it is reflected onto the small intestine as the anterior layer of the mesentery, a fold varying from 5 to 8 in. between its attachments. After surrounding the small intestine it becomes the posterior layer of the mesentery and so again reaches the posterior abdominal wall, down which it runs until it reaches the rectum. The anterior surface of the rectum is covered by peritoneum to a point about three inches from the anus, from which in the female it is reflected onto the uterus and vagina and then onto the bladder; in the male, on the other hand, the reflection is directly from the rectum to the bladder. At the apex of the bladder, after covering the upper surface of that organ, it is lifted off by the urachus and runs up the anterior abdominal wall to the umbilicus, from which the start was made. All this is the greater sac.

The tracing of the lesser sac may be conveniently started at the transverse fissure of the liver, whence the membrane runs down to the stomach as the posterior layer of the lesser omentum, covers the posterior surface of the stomach, passes down as the second layer of the greater omentum and up again as the third layer, covers the anterior surface of the transverse colon and then reaches the pancreas as the anterior layer of the transverse mesocolon. After this it covers the front of the pancreas and in the middle line of the body runs up below the diaphragm to within an inch of the anterior layer of the coronary ligament of the liver. Here it is reflected onto the top of the caudate lobe of the liver to form the posterior layer of the coronary ligament, covers the whole caudate lobe and so reaches the transverse fissure.

This section, therefore, shows two completely closed sacs without any visible communication. In the female, however, the great sac is not absolutely closed, for the upper ends of the uterine (Fallopian) tubes open into it by their minute ostia abdominalia, while the lower ends communicate with the cavity of the uterus and so with the vagina and exterior.

A horizontal section through the upper part of the first lumbar vertebra will, if a fortunate one (*see* fig. 2), pass through the epiploic foramen and show the communication of the two sacs. A starting point may be made from the midabdominal line and the parietal peritoneum traced around the left side of the body wall until the outer edge of the left kidney is reached. Here it passes in front of the kidney and is soon reflected off onto the spleen, which it nearly surrounds. Just before it reaches the hilum of that organ where the vessels enter, it is reflected toward the front of the stomach, forming the anterior layer of the greater omentum. Continuing, it soon reaches the lesser curvature of the stomach and then becomes the anterior layer of the lesser omentum, which continues until the bile duct and portal vein are reached at its right free extremity. Here it turns completely around these structures and runs to the left again, as the posterior layer of the lesser omentum, behind the stomach and then to the spleen again as the posterior layer of the greater omentum. From the spleen it runs to the right once more, in front of the pancreas, until the inferior vena cava is reached. This point is just behind the portal vein and is the place where the lesser and greater sacs communicate, known as the epiploic foramen. From this opening the lesser sac runs to the left, while all the rest of the peritoneal cavity in the section is the greater sac. From the front of the vena cava the parietal peritoneum passes in front of the right kidney and around the right abdominal wall to the midabdominal line. The right part of this section is filled by the liver, which is completely surrounded by a visceral layer of peritoneum, and no reflection is usually seen at this level between it and the parietal layer. Some of the viscera, such as the kidneys and pancreas, are located behind the peritoneum. Others, such as the small intestines and transverse colon, are surrounded, except at one point where they are attached to the dorsal wall by a mesentery or mesocolon, as the reflections are called. Others again are completely surrounded, and of these the caecum is an example. Some, like the liver and bladder, have larger uncovered areas, and here the reflections of the membrane form ligaments that allow considerable freedom of movement.

Each vaginal process is the remains of a peritoneal pocket that

FIG. 2.—HORIZONTAL SECTION, SEEN FROM ABOVE, THROUGH THE UPPER PART OF THE FIRST LUMBAR VERTEBRA, SHOWING ARRANGEMENT OF THE PERITONEUM

descends into the scrotum during fetal life before the testis itself descends. After the descent of the testis the upper part usually becomes obliterated, while the lower part forms a serous sac that nearly surrounds the testis. The parietal layer lines the inner wall of its own side of the scrotum.

**Embryology.**—The middle germ layer (mesoderm) eventually splits into two layers, the outer of which (somatic) then lines the parietal or ectodermal wall, while the inner (splanchnic) overlies the entoderm; between the two is the coelom. The pericardial area is early distinguished from the rest of the coelom since it first lies in front of the neural and buccopharyngeal area; here the mesoderm stretches right across the midline, which it does not do in front and behind. As the head of the embryo is formed the pericardium is gradually turned under, so that the dorsal side becomes the ventral and the anterior limit the posterior (see fig. 3 and 4).

The primitive heart lies at first in the ventral wall of the pericardium, but with the folding under it comes to lie in the dorsal wall and gradually bulges into the coelom (pericardial cavity); in doing this it draws down a fold of the membrane called the dorsal mesocardium. In mammals no ventral mesocardium exists, though in more lowly vertebrates it is present. Caudally the pericardial cavity communicates with the general cavity of the coelom, but with the growth of the Cuvierian ducts (see VEINS: *Embryology*) these communications disappear. Originally the mesocardium runs the whole length of the pericardium from before backward, but later on the middle part becomes obliterated.

Just behind the pericardium the mesoderm forms a mass into which the developing lungs push, thereby protruding into the coelom. These spaces lose connection with the rest of the coelom, as the diaphragm develops, and become the pleural cavities. The rest of the coelom persists as the peritoneal cavity. At first the stomach and intestine form a straight tube, connected to the dorsum of the embryo by a dorsal mesentery and to the mid-ventral wall, cranial to the umbilicus, by a ventral mesentery. Into the ventral mesentery the liver grows as an outgrowth from the duodenum, so that some of the mesentery remains as the falciform ligament of the liver and some as the lesser omentum. Into the dorsal mesentery the pancreas grows, as two diverticula from the duodenum, while the spleen is developed from the mesoderm contained in the same fold. As the stomach turns over and its left side becomes ventral, the dorsal mesentery attached to it is pulled out, so that it forms the greater omentum including the gastrosplenic ligament. The duodenal loop is thrown to the right, so that the right side of its mesentery becomes pressed against the dorsal wall of the abdomen and obliterated. This accounts for the fact that the pancreas and duodenum are covered by peritoneum only on their anterior surfaces in man. The formation of the lesser sac is partly due to the turning of the stomach to the right, with the result that a cave is formed behind it. Originally the whole colon had a dorsal mesocolon continuous with the mesentery, but in the region of the ascending and descending colon this usually disappears and these parts of the gut are uncovered by peritoneum posteriorly. The transverse mesocolon persists and at first is quite free from the greater omentum, but later, in man, the fourth layer of the greater omentum becomes continuous with the posterior layer of the transverse mesocolon.

**Comparative Anatomy.**—In *Amphioxus* the coelom is devel-

FIG. 3.—LONGITUDINAL SECTION SHOWING THE DIFFERENT AREAS OF THE BLASTOCYST IN EARLY DEVELOPMENT OF THE MAMMALIAN EMBRYO

AFTER YOUNG AND ROBINSON, FROM CUNNINGHAM, "TEXT-BOOK OF ANATOMY"

FIG. 4.—LONGITUDINAL SECTION SHOWING RELATION OF PARTS TO SEROUS MEMBRANES IN THE EARLY DEVELOPING EMBRYO OF MAMMALS

oped in the embryo as a series of bilateral pouches from the sides of the alimentary canal; these are therefore entodermal in their origin, as in *sagitta* and the Echinodermata (see ECHINODERMATA) among the invertebrates. In the adult the coelom is represented by two dorsal canals communicating with a ventral canal by means of branchial canals which run down the outer side of the primary gill bars. Into the dorsal canals the nephridia open. In the intestinal region the coelom is present only on the left side.

In the higher chordates (Craniata) the coelom is developed by a splitting of the mesoderm into two layers, and a pericardium is partitioned off from the general cavity. In all groups the ova burst into the coelom before making their way to the exterior, and in some—e.g., *Amphioxus*, lamprey (*Cyclostomata*), eels and lungfish (*Dipnoi*)—the sperm cells do so too. The *Cyclostomata* have a pair of genital pores which lead from the coelom into the urinogenital sinus, and so to the exterior.

In the Elasmobranch fishes there is a pericardio-peritoneal canal forming a communication between these two parts of the coelom; also a large common opening for the two oviducts in the region of the liver, and two openings (abdominal pores) on the surface close to the cloacal aperture. In the Teleostomi (teleostean and ganoid fishes) abdominal pores are rare, but in most Teleostei (bony fishes) the ova pass directly down oviducts, as they do in arthropods, without entering the peritoneal cavity; there is little doubt, however, that these oviducts are originally coelomic in origin. In the *Dipnoi* (lungfish) abdominal pores are found, and probably serve as a passage for the sperm cells, since there are no deferent ducts.

In fishes a complete dorsal mesentery is seldom found in the adult; in many cases it only remains as a tube surrounding the vessels passing to the alimentary canal.

In the Amphibia, reptiles and birds a common cavity contains lungs and abdominal organs, and even in birds the lungs are not completely isolated from the others. In many lizards the comparatively straight intestine, with its continuous dorsal mesentery and ventral mesentery in the anterior part of the abdomen, is very like a stage in the development of the human and other mammalian embryos. In the Mammalia the diaphragm is complete (see DIAPHRAGM) and divides the pleuroperitoneal cavity into its two constituent parts. In the lower mammals the derivatives of the original dorsal mesentery do not undergo as much fusion and obliteration as they do in adult man; the ascending and descending mesocolon are retained, and the transverse mesocolon contracts no adhesion to the greater omentum. It is common, however, to find a fenestrated arrangement of the greater omentum, which shows that its layers have been completely obliterated in many places. In those animals, such as the rabbit, in which the testes are sometimes in the scrotum and sometimes in the abdomen, the communication between the peritoneal cavity and vaginal process remains throughout life. See also ENDOTHELIUM.

**BIBLIOGRAPHY.**—R. F. Blount, "The Peritoneum," in Sir Henry

Morris, *Human Anatomy*, 11th ed. (1953); L. B. Arey, *Developmental Anatomy*, 6th ed. (1954); A. E. Hertzler, *Surgical Pathology of the Peritoneum* (1935); L. J. Wells, "Development of the Human Diaphragm and Pleural Sacs," in *Contributions to Embryology*, No. 236 (1954). (L. B. Arey; X.)

**COELOMATA**, a zoological term denoting those animals that have a true coelom; i.e., a membrane (peritoneum)-lined body cavity or space between the body wall and the internal organs. Animals having no such space, as the flatworms (*Platyhelminthes*), are termed Acoelomata, and those in which this space is not a true coelom are called Pseudocoelomata.

**COELOSTAT**, in astronomy, a mirror driven by clockwork so as to reflect continually the same region of the sky into the field of view of a fixed telescope. The mirror is mounted so as to rotate about an axis in its own plane, which points to the pole of the heavens, and is driven at the rate of one revolution in 48 (sidereal) hours. The image of a star seen in the mirror is then stationary. The device is particularly useful in eclipse expeditions when elaborate equatorial mounting of the telescopes is impossible. Other instruments for somewhat similar purposes are the heliostat and siderostat (*q.v.*).

**COEN, JAN PIETERSZON** (1587–1629), fourth governor general of the Dutch East Indies, was born at Hoorn on Jan. 8, 1587. From 1601 to 1607 he was employed in Rome in the house of the Pescatori, merchants of Dutch origin. In 1607 he was sent to the East Indies as second commercial agent for the Dutch East India company and remained away four years. Sent out in 1612 at the head of a trading expedition, he became a councilor and director-general of the East Indian trade in 1613 and later president at Bantam. In Oct. 1617 he was promoted in succession to Laurens Reaal to the post of governor general, in which capacity, through his vigour and intrepidity, he laid the firm foundation of the Dutch empire in the east. In addition to contending with the declining power of the Portuguese, he was in constant conflict with English merchants fighting for a share in the spice trade. Meanwhile the native rulers sought to play off one power against the other, but Coen reduced them to submission—sometimes, as at Banda (1621), with cruelty. He took and destroyed the original city of Jakarta in 1619 and founded on its ruins the capital of the Dutch East Indies, to which he gave the name of Batavia (now Jakarta, capital of the Republic of Indonesia). Coen resigned his post in 1623 and returned to Holland, but in his absence further difficulties arose with the English, and in 1627, under pressure from the directors of the company, he returned as governor general to Batavia. In 1629 he beat off a formidable attack from the sultan of Mataram upon Batavia, but died, during a second siege, on Sept. 21.

(K. H. D. H.)

**COENWULF** (d. 821), Anglo-Saxon king of the Mercians from 796 to 821, succeeded King Offa's son Egfrith. He managed by 798 to suppress a revolt in Kent against Mercian supremacy and made his brother Cuthred king there, ruling the kingdom himself after Cuthred's death in 807. His harbouring of the enemies of Eardwulf of Northumbria led to an invasion of Mercia in 801. Coenwulf abolished in 802 the archbishopric established (787) in Offa's reign at Lichfield. When Kent was in revolt, he had tried to get the primacy removed from Canterbury to London, but abandoned this scheme after his recovery of Kent. He had a long quarrel with Archbishop Wulfred of Canterbury, which resulted in the latter being debarred from his functions from 817 until a reconciliation with the king in 821. Coenwulf advanced against Wales; the Mercians raided deep into north Wales in 816, and Coenwulf himself took an army into Dyfed in 818. He was at Basingwerk, Flintshire, no doubt campaigning against Wales, when he died in 821.

See F. M. Stenton, *Anglo-Saxon England*, 2nd ed. (1947); *English Historical Documents*, vol. i, ed. by D. Whitelock, pp. 168, 170, 249 ff., 788–794 (1955). (D. Wk.)

**COESITE** is a high-pressure modification of silicon dioxide, or silica ( $\text{SiO}_2$ ), polymorphic with quartz, tridymite and cristobalite. It is named after its discoverer, Loring Coes, Jr., who first produced it in 1953. It is stable only in the region above the pressure-temperature curve between the points at  $0^\circ \text{C}$ . at 20

kilobars and  $1,800^\circ \text{C}$ . at 40 kilobars. For this reason, it would not be expected to be found as a normal mineral in the crust of the earth, for crustal rocks would have to be buried to depths of approximately 100 km. (over 60 mi.) to attain the necessary pressure. In 1960, however, coesite was found in nature as an abundant mineral in the Coconino sandstone of the floor of Meteor crater, near Winslow, Ariz. It is apparent that the coesite was formed from quartz under the elevated temperature and high-pressure conditions induced by the impact of the large meteorite that produced the crater. Since this discovery, coesite has also been found associated with the Rieskessel caldera in Bavaria, a depression that is 13 by 15 mi. across at its bottom, and in several other similar occurrences. The impact origin of these craters thus appears highly probable.

Reported measurements of the specific gravity range between 2.93 and 3.01. It is monoclinic, with  $a = 1.593$ ,  $\gamma = 1.597$  and near 8 in hardness. Unlike the other forms of  $\text{SiO}_2$ , it is insoluble in 5% hydrofluoric acid at room temperature.

**COEUR, JACQUES** (c. 1395–1456), French trader and businessman, who became immensely rich and correspondingly powerful, was born at Bourges, a town of drapers and merchants, where his father was a skinner. About 1429 he formed a commercial partnership with two brothers named Godart; but he was compromised by a fraudulent speculation in coinage, in the contracting for which he had taken a share. In 1432 he initiated himself into the Levant trade, sailing from Narbonne on a ship belonging to merchants of Montpellier; Bertrandon de la Broquière, equerry of Philip the Good, duke of Burgundy, met him at Damascus. After his return he quickly rose to prominence. He was master of the mint in Paris in 1436 and *argentier du roi* (steward of the royal expenditure and banker of the court) three years later. He became a member of the king's council (1442), then commissioner to the estates of Languedoc (1441–51) and inspector general of taxes (*visiteur général des gabelles*) for Languedoc (1447). He inspired the *ordonnances* issued between 1435 and 1451 to withdraw the money that had been stamped with rival French and English superscriptions during the war. Charles VII entrusted him with diplomatic missions: in 1447, Jean de Villages, his nephew, obtained from the sultan of Egypt certain privileges for French merchants and also the right to consular representation; and Jacques Coeur himself managed to maintain good relations with Genoa and won the favour of Pope Nicholas V by his zeal to promote the abdication of the antipope Felix V. In 1449 he lent the king the money necessary for the recovery of Normandy and entered Rouen with him appareled no less magnificently than he. He was then at the height of his glory. Ennobled in 1441, he managed the marriage of his daughter with a nobleman, got his brother made bishop of Luçon and saw his son archbishop of Bourges. He possessed about 40 manors and built a palace at Bourges which remains one of the finest monuments of Gothic domestic architecture in France.

Jacques Coeur's businesses were various but connected. Their basis was Levantine trade; the pope had authorized him to trade with the infidels. At Montpellier, the heart of his activity, he built a house to which were delivered the spices brought by his seven galleys in exchange for scarlet cloth sold to the Levantines. All the chief cities of western Europe supplied and consumed his wares. At Barcelona, Avignon, Lyons, Paris, Limoges, Rouen and Bruges, he had his factors; at Tours was the warehouse of the "Argentier"; and the end of the Hundred Years' War facilitated relations with England and Scotland. He competed with the Italian ports. At the end of his career he used the port of Marseilles. To sustain his enterprises, Jacques Coeur acquired much land and property, used his connections and his political position and received gratifications from the towns and the estates of Languedoc, whose interests he defended. The silver necessary for trading in Levant was provided by the mines of Beaujolais and the Lyonnais that the king had granted to him.

Other merchants, however, were jealous of his quick progress. His debtors, numerous at the court, resolved to disgrace him. He was accused of having poisoned Agnès Sorel, the king's mistress

who had died in 1450; and he was charged with speculation and extortion. Arrested in July 1451 and confined for two years, he was condemned to do public penance for his fault and to remain a prisoner until he should have paid a very heavy sum; and all his possessions were confiscated. He would have remained a prisoner if Jean de Villages had not arranged his escape to Beaucaille and thence to Marseilles, Nice, Pisa and Rome, where the pope received him in 1455. On Nov. 25, 1456, he died at Chios, whither he had gone in command of the fleet sent by Pope Calixtus III to relieve Rhodes. Louis XI, in reaction against his father, considered Jacques Coeur's rehabilitation, returned some of his property to his family and, by taking his agents into his service, revived the enterprises that he had initiated.

(M. M.)

**COEUR D'ALENE**, a tribe of American Indians whose territory included the forested and partially mountainous area around Coeur d'Alene lake, Ida., and the open grasslands of immediately adjacent Washington. They spoke a Salishan language and belonged culturally to the Plateau. Adjoining tribes were: west, the Spokane; north, the Kalispel; east, the Flathead; south, the Nez Percé. All were culturally akin to the Coeur d'Alene and all were Salishan except the Sahaptin-speaking Nez Percé. However, the Coeur d'Alene were clearly distinguished from their neighbours in dialect and in many specialized aspects of their cultural life.

The general Plateau principles of democracy in political organization and of devotion to the guardian spirit in religion were strongly exemplified (see PLATEAU INDIANS). They lived peacefully with all their neighbours. Occasional small-scale raids occurred, but no warfare had taken place from time immemorial.

The origin of the French name for the tribe is uncertain. In the early literature English translations were sometimes used, such as "pointed hearts" or "awl hearts." The untranslatable native name has been commonly rendered as "Skitswish." The form used by the explorers Lewis and Clark was "Skeet-so-mish."

These explorers did not visit the tribe but, on information obtained from the Nez Percé, accurately mapped their location and estimated the population at 2,000. By 1873, when a reservation was established by executive order, the population had dropped to well under 1,000. No treaty was ever made with these Indians, but the loss of the bulk of their tribal lands was recognized in 1887 in an agreement with the United States. In 1955 the U.S. Indian Claims commission affirmed aboriginal Indian title to the lands claimed by the survivors of the tribe. The precise number of survivors is uncertain, but the Indians living on the Coeur d'Alene reservation in the 1960s numbered about 350.

(V. F. R.)

**COFFEE**, a beverage made from the roasted seeds (beans) of the coffee plant, a tropical evergreen shrub or small tree of the genus *Coffea* of the family Rubiaceae (q.v.). Coffee is consumed, as either a hot or cold drink, by about one-third of the world's population in an amount believed larger than that for any other beverage. In the mid-1960s, the U.S. was consuming about 50% and Brazil was producing about 50% of the world's coffee crop.

The popularity of coffee can be attributed at least in part to its invigorating effect. This effect is produced by caffeine, an alkaloid that is present in ground coffee in amounts between 0.75 and 1.5% by weight. In this amount, caffeine functions as a stimulant and diuretic through its actions on the central nervous system, heart, blood vessels and kidneys. Because these effects generally are beneficial, coffee or caffeine may be prescribed in

the treatment of heart disease, dropsy, migraine, chronic asthma and barbiturate poisoning. Excessive amounts of coffee or caffeine may produce excessive gastric acidity, nervousness and heightened cardiac action, but fatal results from overdoses of coffee or caffeine have never been reported in humans, although lethal overdoses can be demonstrated in laboratory animals.

**History.**—Coffee probably derives its name from the Arabic *qahwah*, although some etymologists connect it with the name Kaffa (q.v.), a province in southwest Ethiopia (*Abyssinia*) reputed to be the birthplace of coffee. Coffee plants that are believed to have been growing wild in Kaffa were taken to southern Arabia and placed under cultivation there about 500 years ago. The original name is reflected by the words adopted for coffee in various languages; for example: Chinese, *kai-fey*; Danish and Swedish, *kaffe*; Dutch, *koffie*; Finnish, *kahvi*; French, Spanish and Portuguese, *café*; German, *Kaffee*; Greek, *kaféo*; Hungarian, *kavé*; Italian, *caffè*; Japanese, *kéhi*; Latin (scientific), *coffea*; Persian, *qéhvé*; Polish, *kawa*; Rumanian, *cafea*; Russian, *kophe*; Turkish, *kahveh*.

The history of coffee, although vague and obscure, is rich in legend. One of the tales surrounding the discovery of coffee is that of Kaldi, a goatherd. Bewildered by the queer antics of his flock, Kaldi is supposed (about A.D. 850) to have eaten berries of the evergreen bush on which the goats were feeding and, overjoyed at the feeling of exhilaration that he experienced, has been pictured as dashing off in excitement to proclaim his great find to the world.

The stimulating effect of coffee was soon discovered and taken advantage of in connection with the long religious service of the Muslims, but the strictly orthodox or conservative section of the priesthood claimed that it was an intoxicating beverage and, therefore, prohibited by the Koran. Severe penalties were threatened those disposed to its use. Nevertheless, coffee drinking spread rapidly among Arabian Muslims, and its growth and use became general in Arabia.

The early record of coffee in Europe, where it was introduced into one country after another during the 16th and 17th centuries, is filled with accounts of its use as a religious, political and medical potion, its rises and falls in favour, and its prohibition or approval. Coffee gained its first real popularity as a beverage in the coffeehouses of London, which became centres of political, social, literary and eventually business influence (see LLOYD'S). The first London coffeehouse was established in (or about) 1652 "at St. Michael's Alley in Cornhill" by one Pasqua Rosée and a "quarreling partner" named Bowman, from whom Rosée soon parted.

In the first-known coffee advertisement, a handbill produced in 1652 (original in the British museum), Rosée proclaimed that coffee "quickens the spirits, and makes the heart lightsome . . . is good against sore eyes . . . excellent to prevent and cure the dropsy, gout, and scurvy . . . neither laxative nor restraining."

Continental Europe, too, became well implanted with the idea of coffee, and the coffeehouse flourished in most of these countries later in the 17th century. In the major cities of North America (Boston, New York and Philadelphia), coffeehouses also became popular, starting about 1689. The first licence to sell coffee in the United States was issued to a Dorothy Jones of Boston in 1670. The Merchants' Coffeehouse, established in New York in 1737, is claimed by some authorities to have been the "birthplace of the American Union."

Until the close of the 17th century, the world's rather limited supply of coffee was obtained almost entirely from the province of Yemen in southern Arabia. But, with the increasing popularity of the beverage, the propagation of the plant spread rapidly from southern Arabia to Ceylon (1658), to Java and other islands of the Netherlands Indies starting about 1696, Haiti and Santo Domingo in 1715, Dutch Guiana (Surinam) in 1718, Martinique in 1723, Brazil 1727, Jamaica 1730, Cuba 1748, Puerto Rico 1755, Costa Rica 1779, Venezuela 1784, Mexico 1790, Colombia late 18th century, El Salvador 1840. Coffee cultivation was started in the Hawaiian Islands (Kona district, island of Hawaii) in 1825.

One of the most dramatic stories that explain how coffee was brought to the new world is that of Gabriel Mathieu de Clieu, a

young French naval officer assigned as captain of infantry at Martinique. In 1723 (some authorities set the date as 1720), De Clieu, while on a visit to France, heard that the Dutch had succeeded in transplanting coffee from Arabia to the East Indies; he became determined to carry the cultivation to Martinique, where the climate resembled that of the East Indies. The few coffee plants then being cultivated in Paris were guarded in the royal hothouse of Louis XV. De Clieu obtained one (some writers say two or three) of the precious plants. During his return trip across the Atlantic, De Clieu recorded that for more than a month he was obliged to share his scanty ration of water with his tiny coffee plant (he refers to only one) "upon which my happiest hopes were founded and which was the source of my delight." De Clieu's little tree was finally planted in Martinique and carefully nursed to its first harvest of coffee cherries, from whose seeds a big majority of the coffee plants in the Americas are said to be descended. By 1777, three years after the death of De Clieu, there were nearly 19,000,000 coffee trees in Martinique.

By the 20th century, coffee had become responsible for much of the income of many countries lying between the Tropic of Capricorn and the Tropic of Cancer. Although practically every country within this area produces some coffee, the greatest concentration of production became centred in the western hemisphere.

**Botany of Coffee.**—The genus *Coffea*, to which the common coffee tree belongs, contains 25 or more species, most of which grow wild in the tropics of the old world.

Of the various species, *Coffea arabica* accounts for the bulk of world production. Other species grown commercially are *C. robusta* and *C. liberica*, although production of the latter is very limited in quantity. *C. stenophylla* is not known to have been produced commercially.

The common Arabian coffee shrub (*C. arabica*) is an evergreen plant that under natural conditions may grow to a height of 30 ft. or more. But for commercial purposes, particularly in countries where the coffee cherries are picked by hand, the trees are usually topped to keep heights under 15 ft. so as to make harvesting easier. Leaves of the coffee tree resemble laurel in form (elliptic, 4 to 6 in. in length, 1½ to 2½ in. wide) and have a deep rich-green colour and a glossy surface. The white flowers of the coffee tree, which are produced in dense clusters in the axils of the leaves, have a five-toothed calyx, a tubular five-part corolla, five stamens and a single bifid style. Coffee trees in blossom are things of beauty, but the flowers last only a few days. The flowers are replaced by clusters of green cherries that advance in colour through various shades of green and golden brown until fully ripe, when they are bright red and are similar in shape to ordinary fruit cherries, although somewhat less plump and slightly elongated.

The red outside covering of the coffee cherry is a thick pulpy skin. Under the skin is a layer of yellowish jellylike substance that completely surrounds the two beans or berries, which lie with their flat faces together like the two halves of a peanut. Each bean (also called seed or berry) is enclosed in a membranous endocarp, commonly called the "parchment," which is brittle when dried. Inside the endocarp and completely surrounding each individual coffee bean is a delicate spermoderm (seed skin) commercially called the "silver skin." Malformation frequently produces a single bean called a "pea-berry" that is completely circular and not flat on one side. The coffee bean (seed) is blue-green in colour and has a tough, hard texture.

**Cultivation and Processing of Green Coffee.**—Primitive methods were used in the production of coffee for many years, but by the 20th century the large commercial producers were using intensive cultivation and mechanical processing methods.

**Growth Enemies.**—The coffee tree is susceptible to damage by insect pests and plant diseases. The Ceylon coffee-leaf disease (*Hemileia vastatrix*), a fungoid growth that appeared in Ceylon in 1869 and spread to almost every coffee-producing country, is at least partially to blame for having once destroyed the coffee industry of the old world. The *Stephanoderes* (coffee-bean borer, referred to in Brazil as the "coffee plague" or *broca*), coffee "leaf-

miner," Mediterranean fruit fly and various forms of root disease are other common pests. They are kept under control by rigorous and continuous use of insecticides. Research laboratories and technical stations have been established in the larger producing countries to further the science of coffee-growing by increasing the yield per tree, creating new and improved techniques for fighting leaf rust and other forms of infestation and attempting to develop a frost-resistant coffee tree.

**Cultivation.**—Cultivation of the coffee plant for several hundred years has brought about considerable variations in local types. The colour of coffee beans after harvesting and processing may differ considerably as to shade, and variations in size and shape of the beans make it possible to differentiate commercial types by appearance, although these characteristics are not always indicative of quality "in the cup." In general, it may be said that the greatest differences in the drinking quality of coffee are produced by altitude—the higher the altitude, up to the limit of cultivability, the milder the product. This mildness is believed to be produced by aromatic substances that also contribute to the pleasurable aroma and taste of the beverage.

Coffee is grown under varying weather conditions at altitudes from 1,500 to 6,000 ft., but it is more or less generally conceded that the finest coffees usually come from the higher elevations—3,000 to 6,000 ft. Coffee requires a warm and humid climate, preferably with the sun on the plant only part of the day, which explains why hilly or mountainous countries are preferred for planting trees. The most desirable temperature averages 65° to 75° F. the year around, although coffee grows well in some places where greater variations occur (over 80° or under 60° F.). It should be noted that in tropical countries elevations of 6,000 ft. and above are not accompanied by the extreme low temperatures found at such elevations outside the tropics, although frost-producing temperatures have been recorded in some coffee countries at infrequent intervals and have caused serious damage to the coffee crop.

Coffee trees are planted according to precise plans for spacing but become so dense after a few years that they almost appear to be growing wild. Trees have to be pruned closely to create passageways and permit access at time of picking. The coffee tree begins to produce a small number of cherries when it is three years old but usually does not come into full bearing until its fifth year. A tree may continue to yield profitably for 50 to 60 years, although 25 to 30 years is average, and many growers prefer to replace trees after 12 to 15 years in order to maintain quality and high yield.

The steps involved in the cultivation of coffee differ somewhat from country to country and from locality to locality, but the over-all procedure is generally as follows: coffee trees are propagated either from seeds or from slips. In the latter case, the lower branches of the tree are bent down and the ends are buried in the earth. After about four months, roots form and the new growth starts.

Seeds are usually propagated in carefully prepared nursery beds that are shaded to protect the tender shoots from too much sun as they come through the ground. When seedlings are four to six months old they are transplanted to allow room for development. At about 18 months, when the plants are approximately 20 in. high, they are transplanted for the last time to whatever permanent planting spot has been selected. As the coffee trees continue to grow and begin to reach maturity they require more and more sunshine for proper development and ripening of the cherries; for this reason, the shade trees among which the coffee trees are planted must be pruned frequently.

In some producing countries, coffee cherries are allowed to ripen to a point where they shrivel and begin to dry on the trees and are then shaken off onto large sheets of canvas. The higher grades of coffee, however, are picked by hand when the cherries are at the desired stage of ripeness. Trees are not stripped. Only the ripe cherries are removed, and it takes several pickings before a crop is completely harvested. In some countries the harvesting is entirely seasonal, while in others it is almost a year-round process, several crops being produced each year. Under good

conditions, a fair day's pick per person is from 100 to 125 lb. of coffee cherries. It takes about 5 lb. of cherries to make 1 lb. of green coffee beans, so, in terms of usable coffee, it might be said that a picker's capacity is from 25 to 30 lb. a day. On the average, a coffee tree will produce from 1½ to 2 lb. of green coffee beans a season; thus a plantation must be of rather extensive size to produce tonnage of any great consequence.

**Processing.**—Coffee may be prepared by either a "dry" or a "wash" process. In the "dry" process, sometimes called the "unwashed" or "natural" process, the coffee cherries are thoroughly rinsed in water and then spread out on cement patios in the open air and sun to dry. After drying, the coffee is repeatedly run through fanning and hulling machines to remove the hulls, dried pulp and parchment, and then is subjected to further cleaning by machines that remove portions of the silver skin.

The "wash" process is quite different. The cherries are first put through a pulping machine that breaks them open and virtually squeezes the beans out of the pulpy skin. Then the beans go into large tanks where they are left for about 24 hours. Slight fermentation takes place in the jellylike substance, which the coffee grower calls "honey." This fermentation loosens the honey so it can be removed easily by thorough washing back and forth through several hundred feet of washing canals. After washing, the coffee is spread out in patios to dry. It takes two to three weeks in the sun for the coffee to become thoroughly dried, and during this time it must be continuously turned over so that every bean will be dried. When climatic conditions do not permit drying in the sun, drying machines are employed. Warm air is circulated through the coffee as it revolves in a large perforated drum. When the desired stage of drying has been reached, the coffee beans are put through hulling and polishing machines that crack and remove the brittle parchment and silver skin.

In the case of the highest quality coffees, there is then a careful hand inspection to remove imperfect beans, which is the final step before packing the coffee in bags for shipment to the coffee ports of the world. (In Brazil, coffee is sacked in 60-kg. bags—132.276 lb. In other countries, the shipping unit may vary from about 150 to 165 lb., and in a few instances may run as high as 200 lb. However, the 60-kg. bag is the accepted statistical unit in almost all computations of world production, exports or imports that are expressed in terms of "bags.")

**Tasting and Blending.**—In European countries, where coffee has been sold to a great extent in the whole bean, importers used to make their purchases largely on the basis of the size, colour and other physical characteristics of the bean, although after 1946 this practice became less general. In the U.S., a more selective manner of purchasing was established; coffees are bought primarily on the basis of cup tests for taste and quality. Persons who work as coffee testers must train for years before becoming proficient. Most testers start training at an early age and continue studying almost without interruption, for they must depend entirely upon taste and smell; they devote great attention to the development of those senses. Coffee defies all known chemical tests for evaluation of quality and can be evaluated only by the senses of taste and smell.

**Varieties of Coffee.**—Coffees grown in the various countries differ by types and kind, as well as by grades. In fact, coffees from different plantations in one producing section nearly always show a variety of characteristics. In the parlance of the trade, the terms "Brazils," "milds" and "robustas" are used to describe the three major types of coffee. Brazils apply generally to coffees grown in Brazil. All those grown elsewhere in Central and South America, and most of those grown in Asia and Oceania, are called milds. Most of the Brazils and milds are produced by the *C. arabica* species of tree. The *C. robusta* species, which produces robusta coffee, is a native of the Congo and is more resistant to disease than is *C. arabica*; however, the beverage produced by *C. robusta* is regarded as inferior to *C. arabica*. Much of the increase in coffee production that took place in Africa during and after the late 1940s was produced by plantings of *C. robusta* trees; by the early 1960s the production of *C. robusta* in Africa was four times that of *C. arabica*.

Broadly speaking, the mild coffees are regarded as superior in characteristics to Brazils, although this is not a strictly true differentiation, for a great deal of the product of Brazil is of finer quality than some of the coffees that come from "mild"-producing countries. This is also true with African growths. The mild coffees from British East Africa and some parts of the Congo compare with the best.

Coffee also is described according to characteristics referred to by growers and buyers as hardness or softness, washed or unwashed, high-grown, naturals, etc. The task of the coffee tester is to combine these characteristics, which are obtained from many different lots of coffee, in a way that produces a satisfactory blend.

**Roasting.**—Until coffee is roasted it has none of the flavour or taste generally associated with coffee. Roasting creates the brown colour and transforms the natural chemical constituents into others that give coffee its splendid aromatic qualities and pleasing taste. Full development of the flavour depends to a great degree on the avoidance of underroasting or overroasting. Skill and experience are required to avoid the slight variations that might yield an undesirable result. Green coffee loses about 16% of its weight in the roasting process. Therefore, approximately 1.19 lb. of green coffee is required to produce 1 lb. of roasted coffee; and 1 lb. of green coffee is equivalent to .84 lb. of roasted coffee.

**Grinding.**—Coffees packaged in ground form by the manufacturer go through the grinding process immediately after roasting. In most modern roasting plants, the grinding is accomplished by feeding the coffee through steel rollers that first crack it and then cut it to the desired degree of fineness. Some coffees are left in the whole bean to be ground in the grocery store at time of purchase, or in some cases ground in the home.

Ideas with respect to granulation vary. Some roasters offer their product in several different degrees of grind, each identified as being especially suited for certain types of coffee-brewing devices. Others produce what is referred to as an "all-purpose grind," composed of certain proportions of coarse, medium and fine particles intended to permit proper extraction of the taste and strength elements so that the beverage will be balanced in aroma, flavour and strength no matter what method of preparation is used.

Early in 1948 the national bureau of standards of the United States department of commerce, in co-operation with the National Coffee association of the U.S., issued a Simplified Practice recommendation stipulating three degrees of fineness for standard grinds of coffee (with reasonable tolerances) identified as regular grind, drip grind and fine grind. Adherence to these standards is not mandatory, but they have been followed fairly generally by U.S. roasters who market their product in more than one grind. Regardless of the type of grind, uniformity of granulation is important and various methods of checking, principally with wire screen sieves and sieve shakers, are used to make sure that the proportions of the various-sized grains run uniformly throughout all production.

**Packaging.**—Generally speaking, roasted coffee is sold in bulk, in paper packages or in rigid containers that are either vacuum-packed or pressure-packed. Bulk coffee, distributed through retail outlets in sacks or wooden drums (like the old cracker barrel), is weighed out to the purchaser; this type of marketing had almost disappeared in the United States by the early 1960s. Coffee sold in special types of paper bags or cartons is usually packaged by the manufacturer and distributed over reasonably small geographic areas from central roasting points. Most roasters operating over large areas (and this is particularly true in the United States) pack coffee by the vacuum process either in metal cans or in glass jars. This is done immediately after roasting and grinding.

Ground coffee begins to lose freshness when exposed to the air because of oxidation of the chemical ingredients that provide the flavour and aroma. The vacuum-packing process, first applied to the packaging of coffee in 1900 by a firm in San Francisco, Calif., protects the quality of coffee over a long period of time and enables the manufacturer to preserve the flavour and freshness of coffee

ground in his plant immediately after roasting. After the can or jar is filled with ground coffee, the air is withdrawn from the container, which is then hermetically sealed, thereby preventing the entrance of air until the container is opened. The same result is achieved by pressure packing, the main difference being the introduction of an inert gas into the can after the air is withdrawn and before the can is sealed. By the early 1960s, approximately two-thirds of all the home-consumed ground coffee in the United States was vacuum-packed, mostly in metal cans.

**Soluble Coffee.**—Soluble coffee is a powdered or liquid form of brewed coffee concentrate to which water is added to produce the beverage. There are three types of soluble coffee: (1) dried or dehydrated; (2) liquid extract; (3) frozen concentrate. Liquid coffee extract (packaged either in jars, cans or pressurized aerosol dispensers) had not, by the early 1960s, proved very practical or successful, largely because it required refrigeration during distribution and exhibited a tendency to deteriorate. Frozen concentrate likewise had not made any notable progress. Most soluble coffee consumed in the early 1960s was of the dried type.

Although patents on powdered or liquid coffee concentrate or essence were first issued in the early 19th century (mostly in Europe), such a product did not become a commercial reality until G. Washington, an American chemist residing temporarily in Guatemala city, invented a "refined soluble coffee" in 1906 that was first sold in the United States in 1909. Prior to World War II, soluble coffee was a relatively negligible factor in the coffee industry. Its popularity, however, was considerably enhanced in the U.S. when it was used by the U.S. armed forces in field rations; after the war several companies that had begun to produce such a product for military supply began to market commercial brands of "instant coffee," so-called because it could be prepared as the beverage simply by adding hot water. Soluble coffee advanced from a relatively modest position in 1946 until by the early 1960s between  $\frac{1}{4}$  and  $\frac{1}{3}$  of all coffee prepared in U.S. homes was of the soluble type. During this time, most roasters of national or regional importance, and including some with only localized distribution, had either developed their own facilities for producing soluble coffee or acquired such a product from a producer for the trade (private-label packer).

In its early period of rapid growth, soluble coffee in dry form (referred to as powdered or granular) was either all coffee or what is known as product or filled type (coffee with carbohydrates added). With continuing improvement in the quality of soluble coffee, a distinct consumer preference began to be evidenced in favour of the all-coffee type and by the mid-1950s the product type had practically disappeared from the U.S. market.

The manufacturing of soluble coffee is an intricate process that varies considerably from company to company according to their process and equipment. Generally speaking, however, soluble coffee is produced by first blending, roasting and grinding as in the case of regular ground coffee. Then follow extraction, evaporation and drying (for powdered instant coffee) by one of several methods, the two systems most commonly used being spray drying and drum (or belt) drying in vacuum. Varying percentages of extraction and differences in methods of evaporation and drying produce instant coffees that differ in colour, type and fineness of particles, and density. The finished product is packaged by automatic machinery either in glass jars or cans, glass containers being in common use in the early 1960s.

**Decaffeinated Coffee.**—A process was developed in Germany about 1900 by Ludwig Roselius, a coffee merchant, for removing a large percentage of the caffeine from coffee. His technique was later improved by manufacturers in the United States. Although the processes for decaffeination remain more or less secret, it may be said that the result is attained by steaming the green coffee and then soaking it in a chlorinated organic solvent. During the 1950s, preference in decaffeinated coffee shifted markedly from the ground to the soluble (instant) product, and in the early 1960s about  $\frac{1}{2}$  of all soluble coffee consumed in homes was decaffeinated. Ground and instant decaffeinated coffee together accounted for about  $\frac{1}{10}$  of the coffee used in U.S. homes.

**World Production.**—In the first half of the 20th century, after

the centre of coffee production shifted away from Arabia and other sections of the old world, the countries of the western hemisphere grew up to nearly 90% of all the coffee produced in the world. After 1950, the western hemisphere's share of world production dropped to approximately 75%, chiefly because of the increased rate of coffee growing in Africa. Brazil continued to rank, however, as the world's largest producer of coffee, growing about 40,000,000 bags annually (1 bag = 132.3 lb., or 60 kg.). Other leading producers were Colombia, Ivory Coast, Togo, Mexico, Angola, Guatemala, El Salvador, Indonesia, Costa Rica and India. World production of coffee averages about 77,000,000 bags a year; about 80% of the crop is exported. The United States accounts for about 55% of the world imports; other major importing countries are France, Germany, Italy, Sweden, Canada and Great Britain.

**Inter-American and International Coffee Agreements.**—Early in World War II (May 1940) almost all of the European coffee market was cut off, and it became necessary for producers to attempt to sell their entire output to the United States. In the wake of enormous overproduction, there followed a price disruption that threatened the economic stability of the producing countries. The purpose of the Inter-American Coffee agreement, drawn up between the governments of the United States and 14 Latin-American coffee-producing countries on Nov. 28, 1940, was to make possible the orderly marketing of coffee under the conditions then existing. The agreement provided for equitable allocation of the United States coffee market among the participating countries through limitation of exports by the Latin-American signatories according to a basic annual quota. The agreement expired Sept. 30, 1948. Thereafter, the Special Commission on Coffee was established within the Inter-American Economic and Social council in order that the United States and representatives of producing countries of the western hemisphere might continue to have the opportunity to discuss problems of mutual concern affecting coffee.

A new imbalance between production and consumption appeared in the late 1950s when crops began to be produced by the extensive new plantings that had been made in 1953–54, the year of crop damage and record high prices. In an effort to forestall a new price disruption, a Latin-American Coffee agreement was entered into by 15 western hemisphere producing countries in Oct. 1958. In Sept. 1959, these same countries joined with some of the African producers to create the International Coffee agreement, which was renewable on a year-to-year basis but aimed at eventually becoming a long-term arrangement that would include all producing countries. The objective was to stabilize the world coffee market through self-imposed export quotas and renewed efforts to increase consumption. These objectives were to be reached through more aggressive propaganda in the United States and active development of "new markets" as distinguished from "traditional" coffee-consuming countries.

**How to Make Coffee.**—The Coffee Brewing Institute, Inc., a nonprofit membership corporation formed in 1952 by the Pan-American Coffee bureau and the National Coffee association of U.S., recommends observance of the following simple rules in making coffee: (1) Start with a thoroughly clean coffee maker. Rinse with hot water before using. Wash thoroughly after each use. Rinse with hot water and dry. (2) Use fresh coffee. Buy coffee in the size of can or package that will be used within a week after opening. (3) For best results start with freshly drawn cold water. (4) Use the full capacity of the coffee maker. For lesser quantities, it is best to use a smaller coffee maker. Never, in any case, brew less than three-fourths of the coffee maker's capacity. (5) Measure both coffee and water accurately. Standard recommendation for full-strength beverage is two level tablespoons of coffee to each  $\frac{1}{2}$  measuring cup (6 oz.) of water. (6) After finding the exact timing that produces the desired results with a specific coffee maker, stick to it in order to get a uniform beverage. (7) Coffee should never be boiled. When coffee is boiled, an undesirable flavour change takes place. (8) Serve coffee as soon as possible after brewing. Freshly brewed coffee always tastes best. If necessary to let coffee stand for any length of time after

making, hold at serving temperature by placing the utensil in a pan of hot water over very low heat. Electrical devices usually have a "warm" unit for maintaining temperature.

**Making Soluble (Instant) Coffee.**—Soluble coffee can be prepared for individual servings right in the cup, or several cups at a time in any clean utensil, simply by adding the desired amount of boiling water to a measured amount of instant coffee and stirring. It is preferable to pour the water onto the coffee rather than measure the coffee into the water.

Most directions for preparing instant coffee call for "about 1 teaspoon to each cup of water." The exact amount depends on the size of cup, individual strength preference and the coffee itself. The degree of concentration is not the same in various soluble coffees, so larger or smaller measurements of one product may be required than of another to produce equivalent strength.

To prepare iced coffee, place the instant coffee in a glass, half fill with cold water, stir, and fill with ice. Quantities can be made similarly in a larger utensil.

**COFFERDAM**, a temporary dam formed to enable foundations to be laid or other construction operations to be undertaken on a site which is under water. The engineer surrounds the site with an enclosure in such a fashion as to make possible its dewatering.

When the depth of the water is small and the current slight, simple clay dams may be used, but in general cofferdams are somewhat more complicated structures. One type consists of two rows of continuous wooden piles tied together at the top and filled between with clay puddle. Another frequently used type consists of adjacent cells whose continuous outside walls consist of interlocking vertical sheet steel piling. They are also often filled with packed clay puddle. These cells join one another in such a way as to surround the site of the structure to be erected. The enclosed space may then be pumped dry. A cofferdam must be sufficiently strong to withstand the exterior pressures which arise under these circumstances. See also **FOUNDATIONS, STRUCTURAL; TUNNEL**. (W. E. Hd.)

**COFFEYVILLE**, a city of Montgomery county in southeastern Kansas, U.S., on the Verdigris river, about 150 mi. S. of Topeka, near the southern boundary of the state. Founded in 1869 and incorporated in 1872, it was named for James A. Coffey, a pioneer settler. During the early 1870s, following the completion of a railroad, Coffeyville became a major shipping point for Texas cattle and later developed into an important trading and industrial centre.

The city is located in the mid-continent gas and oil field (natural gas was discovered in 1892) and numbers among its industries a refinery, a pipeline terminal and several manufacturers of oil-field equipment. Its industries include tile and pottery manufacture, railroad car repair, flour and soybean milling and preparation of paint pigments and zinc sulfate. The city supports Coffeyville college, a public two-year college. For comparative population figures see table in **KANSAS: Population**. (R. W. Ri.)

**COFFIN, HENRY SLOANE** (1877–1954), U.S. clergyman, author and educator, a leader in the movement for liberal evangelicalism in the Protestant churches, was born in New York city on Jan. 5, 1877. Graduating from Yale in 1897, he studied theology at New college, Edinburgh, Scot. (1897–99), at Marburg, Ger. (1899), and at Union Theological seminary, New York city (1899–1900). After serving as minister of Bedford Park Presbyterian church (1900–05) and Madison Avenue Presbyterian church (1905–06), he became in 1926 president of Union Theological seminary, holding this office till 1945. A many-sided man of great intellectual power and unusual charm, in great demand as

a preacher in college and university chapels, Coffin was an advocate of the application of Christian ethics to social problems, an interpreter of the Reformed tradition of dignity and intellectual integrity in worship, a promoter of higher standards of theological education, a supporter of the League of Nations and of the United Nations, and a tireless worker and negotiator in the cause of Christian unity.

From 1922 until 1945 he served as a fellow of the Corporation of Yale university. He was moderator of the Presbyterian Church in the U.S.A. during 1943–44. He held many distinguished lectureships and was the author of more than 20 volumes in the field of theology and religion, *The Meaning of the Cross* (1931) in particular having been widely recognized as a fine statement of Christian theology for the general reader. He died at Lakeville, Conn., on Nov. 25, 1954.

See Reinhold Niebuhr (ed.), *This Ministry: the Contribution of Henry Sloane Coffin* (1945); and Walter Russell Bowie (ed.), *Joy in Believing: Selections From the Spoken and Written Words and the Prayers of Henry Sloane Coffin* (1956). (M. P. No.)

**COFFIN**, the receptacle in which a corpse is confined (Lat. *cophinus*, a coffer, chest or basket, but not "coffin" in its present sense). The Greeks and Romans disposed of their dead both by burial and by cremation. Greek coffins varied in shape, being in the form of an urn, hexagonal or like modern coffins, or triangular, the body being in a sitting posture. The material used was generally burnt clay, and in some cases this obviously had been molded around the body and baked. In the Christian era stone coffins came into use. Examples of these have frequently been dug up in England. Those Romans who were rich enough had their coffins made of a limestone brought from Assus, in Asia Minor, which was commonly believed to "eat" the body; hence arose the name sarcophagus (*q.v.*).

The coffins of the Chaldeans were generally clay urns with the top left open, thus resembling immense jars; these were molded around the body, since the size of the mouth would prevent insertion after the clay was baked. The Egyptian coffins, or sarcophagi, as they have been incorrectly called, were the largest stone coffins known and were generally highly polished and covered with hieroglyphics, usually a history of the deceased. Mummy chests shaped

to the form of the body were also used, being made of hardwood or painted papier-mâché, and bore hieroglyphics (see **MUMMY**). Unhewn flat stones were sometimes used by early European peoples to line the grave. One was placed at the bottom, others were stood on edge to form the sides, and a large slab was put on top, thus forming a rude cist. In England after the Roman invasion these rude cists gave place to the stone coffin, which was used until the 16th century.

Primitive wooden coffins were formed of a tree trunk that had been split down the centre and hollowed out—a type still in use among aboriginal peoples. The earliest specimen of this type is in the Copenhagen museum, the implements found in it proving that it belonged to the Bronze Age. This type of coffin, modified by planing, was used in medieval Britain by those who could not

afford stone, while the poor were buried without coffins, wrapped simply in cloth or even covered only with hay and flowers. Toward the end of the 17th century, coffins became usual for all classes.

Among the American Indians some tribes, e.g., the Sauk, Fox and Sioux, used rough-hewn wooden coffins; others, such as the Seri, sometimes enclosed the corpse between the upper and lower shells of a turtle. The Seminoles of Florida used no coffins, while at Santa Barbara, Calif., canoes containing corpses have been found buried, though they may have been intended for the dead warrior's use in the next world. Rough stone cists, too, have been found in Illinois and Kentucky. In their tree and scaffold burial the Indians sometimes used wooden coffins or travois baskets, or simply wrapped the bodies in blankets. Canoes, mounted on a scaffold near a river, were used as coffins by some tribes, while others placed the corpse in a canoe or wicker basket and floated it out into the stream or lake. The aborigines of Australia generally used coffins of bark, but some tribes employed baskets of wicker-work.

Lead coffins were used in Europe in the middle ages, shaped like the mummy chests of ancient Egypt. Iron coffins were certainly used in England and Scotland as late as the 17th century.

The coffins used in England are generally hexagonal in shape, of elm or oak lined with lead, or with a leaden shell. In the United States glass is sometimes used for the lids, and the inside is lined with copper or zinc. The coffins of France and Germany and the continent in general usually have sides and ends parallel. Coffins used in cremation throughout the civilized world are of some light material easily consumed and yielding little ash. Ordinary thin deal and papier-mâché are the favourite materials. Coffins for what is known as earth-to-earth burial (i.e., burial in which earth comes into contact with the corpse) are made of wickerwork covered with a thin layer of papier-mâché over cloth.

**COGGESHALL, RALPH OF** (d. after 1227), English monastic chronicler, was a monk of the Cistercian abbey at Coggeshall in Essex. He was elected abbot in 1207, but resigned his office on grounds of ill health in 1218. The abbey already possessed its own *Chronicon Anglicanum*, beginning at 1066; Ralph wrote the entries between the years 1187 and 1224. He wrote a continuation of Ralph Niger's chronicle, extending from 1162 to 1178, and some short annals from 1066 to 1223.

**BIBLIOGRAPHY.**—For texts see *Radulphi de Coggeshall chronicon Anglicanum*, ed. by J. Stevenson (1875); *Radulphi Nigri chronicon ab initio mundi ad A.D. 1199*, ed. by R. Anstruther (1851). On the structure of the *Chronicon Anglicanum* see F. M. Powicke, "Roger of Wendover and the Coggeshall Chronicle," *English Historical Review*, vol. xxi (1906).

**COGIDUMNUS** (COGIDUENUS), a native prince in Roman Britain who flourished in the third quarter of the 1st century A.D. His capital was at Chichester (Noviomagus Regnensium or Regnum), the tribal centre of a people known as Regni or Regnenses, that is, the people of the *regnum* or "kingdom." This comprised, according to Tacitus in *Agricola*, ch. 14, more than one canton. Chichester boasts a famous inscription, set up *ex auctoritate Ti(beri) Claud(i) Cogidubni r(egis) legati Aug(usti) in Brit(annia)*; and this not only indicates his kingship and Roman

citizenship but also his special position in the counsels of the province as an imperial legate. His fidelity to Rome is emphasized by Tacitus.

(I. A. Rd.)

**COGNAC**, a town of western France, *département* of Charente (*q.v.*), is situated on the left bank of the Charente river, 37 km. (23 mi.) W.N.W. of Angoulême. Pop. (1954) 16,843. The 12th-century church of St. Léger has a Romanesque façade and a 15th-century tower. The château, dating from the 15th and 16th centuries, is the former residence of the counts of Angoulême. Cognac is on the main railway from Angoulême to Saintes, Rochefort and La Rochelle. The most important industry is the distilling of cognac, to which the town gives its name and which is exported by rail or through the nearby port of Tonnay-Charente (see BRANDY). Casks and bottles for cognac are manufactured, and there is much trade in grain and cattle.

In 1526 Cognac gave its name to a treaty drawn up in opposition to Charles V by Francis I, the pope, Venice and Milan. Its possession was contested during the wars of religion, and in 1570 it became a Huguenot stronghold. In 1651 it withstood successfully a siege against Louis II, prince of Condé, leader of the Fronde. In World War II the town was in German hands from June 1940 to Aug. 1944.

**COGNITION** means "knowing," in the widest sense of the term. In psychology it is used to denote one of the three ultimate functions or processes of consciousness, the others being feeling and conation (or willing). Cognition includes every mental process that can be described as an experience of knowing as distinguished from an experience of feeling or of willing; it includes, in short, all processes of consciousness by which knowledge is built up. In its most familiar and fully developed form it is known as judgment, in which a certain object (known logically and grammatically as a "subject") is discriminated from other objects and characterized by some concept or concepts. Although cognition is readily distinguishable from feeling and conation, yet in the actual flow of mental life the three types of experience are always found together, not separate, but one of them is usually predominant in one total experience, another in another, and this fact facilitates their mutual discrimination. Psychology, as a descriptive science, is not concerned with the epistemological question, how external objects can be revealed in subjective experiences; it simply takes at their face value these cognitive experiences in which objects appear to be known somehow, and leaves the critical problems to epistemology and logic.

See PSYCHOLOGY, and KNOWLEDGE, THEORY OF, and authorities there quoted.

**COHAN, GEORGE M(ICHAEL)** (1878–1942), U.S. actor, popular song writer, playwright and producer became famous as the "Yankee Doodle Dandy." Though he was born in Providence, R.I., on July 3, 1878, his father foresightedly gave it as July 4. His parents were of the theatrical profession, and at an early age he appeared with them in juvenile parts, subsequently taking comedy roles in vaudeville and on the legitimate stage. Also at an early age he began writing plays and popular songs. A description of his early experiments and the stage career of the "Four Cohans" is in his autobiography, *Twenty Years on Broadway and the Years It Took to Get There* (1925).

Among Cohan's productions may be mentioned *The Governor's Son* (1901); *Forty-five Minutes From Broadway* (1905); *The Talk of New York* (1907); *Get-Rich-Quick Wallingford* (1910); *Broadway Jones* (1912); *Seven Keys to Baldpate*, (1913); *The Tavern* (1921); *The Song and Dance Man* (1923); *American Born* (1925). Among his best-known appearances were those in *Ah Wilderness!* (1933) and *I'd Rather Be Right* (1937). He composed numerous songs, including "Mary's a Grand Old Name," "You're a Grand Old Flag" and the famous "Over There" of World War I, for which congress authorized him a special medal in 1940. Cohan died in New York city on Nov. 5, 1942. His career was the subject of a motion picture, *Yankee Doodle Dandy* (1942).

See Ward Morehouse, *George M. Cohan: Prince of the American Theatre* (1943).

**COHEN, ERNST JULIUS** (1869–1944), Dutch chemist, whose most important work was on the allotropy of metals, par-

ticularly tin. Born at Amsterdam, Neth., on March 7, 1869, he studied chemistry under Svante Arrhenius at Stockholm, Swed., Henri Moissan at Paris, and Jacobus van't Hoff at Amsterdam. He became assistant to the latter in the university chemical laboratories at Amsterdam in 1893, and in 1902 professor of physical chemistry at the University of Utrecht. Cohen headed the Van't Hoff laboratory founded there in 1904. He published a large number of works on piezochemistry and electrochemical thermodynamics, particularly in relation to the study of standard galvanic cells; he also wrote widely on the history of science. During World War II he was arrested by the Germans because of his Jewish descent and died in the gas chamber at the concentration camp of Auschwitz, Ger., on or about March 15, 1944. Cohen's writings include: *Physical Chemistry for Biologists*, *Inorganic Chemistry for Medical Students* (1907); *Jacobus Henricus van't Hoff, Sein Leben und Werke* (1912); *Physico-Chemical Metamorphosis and Some Problems in Piezochemistry* (1928).

**COHEN, HERMANN** (1842–1918), German-Jewish philosopher, founder of the Marburg school of Neo-Kantianism, was born at Coswig, Anhalt, on July 4, 1842, and educated at Breslau and Berlin. In 1876 he succeeded F. A. Lange (q.v.) as professor at Marburg university. Between 1902 and 1912 he published the three parts of his philosophical system (*Logik der reinen Erkenntnis*, *Ethik des reinen Willens*, *Ästhetik des reinen Gefühls*). As a reaction to both metaphysics and materialism, Neo-Kantianism restored the sovereignty of "pure" thought; existence is rooted in reason. The concept of the "thing in itself" (*Ding an sich*), Kant's concession to metaphysics, is to be discarded as being outside human knowledge. In his ethics, Cohen maintained man's absolute freedom. The state aims at the moral perfection of society. God is the "idea," expressing the correspondence between the realms of nature and morality. The realization that philosophical ethics deals with mankind as a whole, not with the individual, caused Cohen's radical turn to religion and to his ancestral Jewish faith. In *Religion der Vernunft aus den Quellen des Judentums* (1918) a systematic presentation of Judaism, he concentrated on the "correlation" between God and the individual, divine love and messianic humanity. After retiring from Marburg (1912), Cohen taught Jewish philosophy at the liberal Institute for the Science of Judaism in Berlin. He died at Berlin, April 4, 1918. See also JEWISH PHILOSOPHY: *Modern Jewish Philosophy*; NEO-KANTIANISM.

See the introduction by Franz Rosenzweig to Cohen's *Jüdische Schriften* (1924); S. H. Bergman, "Hermann Cohen," *Between East and West* (1958). (N. N. G.)

**COHEN** (Hebrew for "priest"), a Jewish family name, implying descent from Aaron and the Hebrew priests. Many families claiming such descent are, however, not named Cohen. Other forms of the name are Cohn, Cowen, Kahn, etc.

**COHESION**: see SOLID STATE PHYSICS; SURFACE TENSION.

**COHN, FERDINAND JULIUS** (1828–1898), German botanist whose studies on microscopic forms of plant life entitle him to rank with Louis Pasteur and Robert Koch as one of the founders of the science of bacteriology. He was born in Breslau on Jan. 24, 1828, completed his higher education at the University of Berlin and then returned to his native city, where he ultimately became director of the Institute of Plant Physiology in the University of Breslau.

Chief among his contributions are his system of classification of microorganisms (1872, 1875), his discovery of bacterial spores (1876) and the bearing of bacterial spores on the problem of spontaneous generation. From his accurate morphologic studies Cohn concluded that it should be possible to arrange bacteria into genera and species. Nevertheless, he pointed out that morphology alone was an insufficient basis for classification. Indeed he was perhaps the first to recognize that organisms of similar form can and do differ from each other in their physiological and biochemical characteristics. During his lifetime Cohn was recognized as the foremost systematic student of bacteria of his day. It was in his laboratory in 1876 that Robert Koch, then unknown, demonstrated his proofs that *Bacillus anthracis* was the causative agent of splenic fever or anthrax, a disease of cattle, sheep and sometimes men. Through Cohn, Koch was appointed to the Imperial

Health office in Berlin, where he continued his brilliant work. Cohn was an outstanding teacher and popularizer of science. He received many honours, among them election as a foreign member of the Royal society of London. Cohn died in Breslau on June 25, 1898.

See Pauline Cohn, *Ferdinand Cohn, Blätter der Erinnerung* (1901); F. J. Cohn, *Bacteria: the Smallest of Living Organisms* (1872), trans. by C. S. Dolley (1881), with bibliography of Cohn's writings in 1939 ed. (M. C. L.)

**COHNHEIM, JULIUS FRIEDRICH** (1839–1884), German pathologist, noted especially for his study of inflammation of the serous membranes, was born at Demmin, Pomorze, on July 20, 1839. After serving as an army surgeon in 1864–65 he became an assistant in the Pathological institute in Berlin and was the most distinguished of Rudolf Virchow's pupils. He was subsequently professor of pathology at Kiel (1868), Breslau (1872) and Leipzig (1878), where he was also director of the Pathological institute. Paul Ehrlich was among his pupils at Breslau. Cohnheim's first important dissertation on inflammation of serous membranes appeared in 1861, and was followed by other important papers on that subject from 1867 to 1873. On this question his teaching was opposed to that of Virchow. He showed that inflammation is caused by the passage of white corpuscles through the walls of the capillaries and that pus is formed largely of these corpuscles in a disintegrated state. Cohnheim made many useful innovations in the method of microscopical work. His most important book is his *Vorlesungen über allgemeine Pathologie* (1878). He died on Aug. 15, 1884, at Leipzig.

**COHOES**, a city of Albany county, N.Y., U.S., part of the Albany-Schenectady-Troy standard metropolitan statistical area, located on the Mohawk river where it tumbles down the "Great Falls" into the Hudson. The history of the city has been determined largely by its location on these falls. Established by settlers from Rensselaerwyck during the early 18th century, Cohoes developed into a small, thriving manufacturing city producing a variety of products, particularly textiles. These enterprises developed because a dam had been built at the falls and because the Erie and Champlain canals had been joined just outside the city by 1825. Capitalists were quick to take advantage of this opportunity for transportation and water power and Cohoes was incorporated as a village in 1848 and as a city in 1869. The old colonial military road from Albany to Ft. Edward and Lake George runs through the city.

In 1866 construction workers found an almost perfect skeleton of a mastodon buried in rock alongside the falls.

For comparative population figures see table in NEW YORK: *Population*. (H. S. Pr.)

**CO-HONG**. This pidgin-English term is generally used to designate the group of Chinese merchant firms authorized by the government to trade with western merchants at Canton before the first Opium War of 1839–42 opened China to more extensive contact with the west. Such firms were called "foreign-trade firms" (*yang-hang*) and the merchants who headed them "hong merchants" (*hang-shang*). These officially sponsored merchants, in existence in the second half of the 17th century, were theoretically 13 in number, but actually there were fewer, sometimes no more than 4. In the 1740s a system was established requiring each foreign ship arriving at Canton to have a hong merchant serve as security, guaranteeing to the Chinese government all duties and the good behaviour of the foreign traders. By 1760, when Canton had become the only Chinese port where foreigners were permitted to trade, the hong merchants were designated as the only merchants in Canton who could sell tea and silk to westerners. A few, like the famous Howqua (Wu Ping-chien; 1769–1843), attained great wealth; but hong merchants were subject to heavy exactions from officials and many failed financially.

The Co-hong has often been compared with a merchant guild. However, while the hong merchants collectively enjoyed the monopoly of the foreign trade at Canton, each merchant was independent in his dealings. As early as 1720 the hong merchants were known to have agreed upon a system of collective price fixing, having taken a blood oath in a manner reminiscent of

Chinese merchant guilds. That arrangement was abandoned in 1722. It was not until 1760 that, under the leadership of an ambitious Hoppo (the official who headed the Canton maritime customs), the hong merchants formed an association called the "collective firm" (*kung-hang*). That association was abolished, however, in 1771 and subsequent attempts to revive it never succeeded. The Chinese term *kung-hang* carried a sense of a price-fixing association; but its pidgin-English corruption, the Co-hong, came to be used by the western merchants in a broader sense, without the connotation of an association. (K.-C. L.)

**COHORT** (Lat. *cohors*, an "enclosure"), the tactical infantry unit of the Roman legion (*q.v.*), which numbered ten cohorts. The cohort corresponded to the modern infantry battalion; it was divided into three maniples (companies), each of which was in turn divided into two centuries (platoons). The size of a cohort varied with the strength of the legion, which in theory had 6,000 men. During the republic, however, a legion of 4,200 men had ten cohorts of 420 men each; during the empire the cohort regained its full strength of 600 men. The organization of the Roman legion into cohorts greatly increased its tactical flexibility over the Greek phalanx. Unlike the phalanx, the legion, because of its cohorts, was able to fight in an open, checkerboard formation readily adaptable to rough terrain and to changes in the tactical situation. The cohort was also the organizational unit of Rome's fire brigade (*vigiles*) and of the city's military garrison, the praetorian guard. See also TACTICS: *Tactics of the Ancient World*. (Do. A.)

**COHOSH**, a common name applied to several plants, including the species of *Actaea* that are better known as baneberry (*q.v.*), the summer cohosh (*Cimicifuga americana*), the black cohosh (*C. racemosa*), all of the crowfoot family, and the blue cohosh (*Caulophyllum thalictroides*) of the barberry family. All occur in eastern North America, with the species of *Actaea* occurring as far west as Utah and Oregon. (J. M. BL.)

**COIMBATORE**, a municipality and district headquarters in Madras state, India, and one of the most important industrial and trading centres in south India. Pop. (1961) 286,305. Located on the edge of a cotton area, it commands the famous Palghat gap, about 20 mi. wide, between the Nilgiris hills to the north and the Anaimalai hills to the south. It is an important textile centre, and its other industries include leather tanning, the manufacture of soap and agricultural implements, and coffee and sugar processing. It has a degree-granting college, an agricultural college and a school of forestry, affiliated with Madras university. Coimbatore is an important railway junction of the Southern railway, providing access through the Palghat gap with the western coast, and is also an important bus terminus, with services to Mysore city. Three miles from the town is the temple of Perur, dating partly from Chola times and partly from the early 18th century.

COIMBATORE DISTRICT (area 6,018 sq.mi.; pop. [1961] 3,557,471) comprises a hilly region on the west, north and south; the eastern part is a fertile plain, lying at an altitude of about 900 ft. The climate is subhumid and hot. Droughts are not uncommon, and during periods of severe drought the small rivers become dry. The hilly west and north is devoted to coffee and tea plantations, and the forest yields good sandalwood and timber. In the plain region rice is an irrigated crop, and cotton, the most important cash crop, is extensively grown. The district, with parts of modern Salem district of Madras state, was formerly named Kongu Nadu and in the 9th century was under the Chola dynasty (*q.v.*). In the 11th century the Hoysala (*q.v.*) kings of Mysore ruled it, and it later formed part of the great 14th-century kingdom of Vijayanagar (*q.v.*). It was conquered by Haidar Ali in 1761 and merged with his Mysore kingdom. After the fall of his son and successor Tipu Sahib (1799) the district became a part of British India and was incorporated in Madras state. In 1956, upon the reorganization of the state boundaries in the republic of India, the taluk of Kollegal was transferred to Mysore state. (G. K. GH.)

**COIMBRA**, the university city of Portugal, is situated in the centre of the country in the province of Beira Litoral, on the right bank of the Mondego river. It is 224 km. (139 mi.) N.N.E. of Lisbon by road, on the main Oporto-Lisbon railroad. Pop.

(1960) 50,168. Founded in 1290 in Lisbon, the university, after being moved several times, was finally settled at Coimbra in 1537. Its chapel has a beautiful door (1517-22) and the richly decorated baroque library (1716-23) possesses 1,000,000 volumes and 3,000 manuscripts, among them a first edition of Luís de Camões' *Os Lusíades* (1572). In the old part of the city, on a hill above the river, are the old Romanesque cathedral (1170); the church of São Salvador (12th century); the architecturally uninteresting new cathedral, begun in 1598; the Machado de Castro museum in the old episcopal palace, restored in 1592; Santa Cruz church, built in the reign of Afonso I and rebuilt in 1520; the aqueduct of São Sebastião (1568-70), rebuilt on Roman foundations; the botanical gardens; the 12th-century monastery of Celas, built by Princess Sancha, daughter of King Sancho I; and Santo António church, remarkable for the pottery sculptures in its chapels. On the right bank of the Mondego near Santa Clara bridge is Dr. Manuel Braga park. On the other side are the old and new convents of Santa Clara, 13th and 17th century respectively, in whose church is the tomb of St. Elizabeth of Portugal, patroness of Coimbra; the Quinta das Lágrimas where Inês de Castro, beloved of King Pedro I, was supposed to have been murdered; and the Lapa dos Esteios. The main industries are the making of pottery, fabrics, foodstuffs, beer, wine and paper. Tanning is carried on. Oil is found and maize, rice and fruits are grown in the district.

A 4th-century Latin inscription identifies Coimbra with Aeminium, while Condeixa, 13 km. (8 mi.) S.S.W., was the ancient Conimbriga or Conimbrica. Aeminium was for more than a century a Moorish stronghold, but in 878 it was recaptured by Alfonso III and peopled by Galicians from the north. When the see of Conimbriga was transferred there, the bishop kept the old name and Aeminium became known as Coimbra. After many vicissitudes, it was captured by Ferdinand I of Castile in 1064 and for more than a century was the centre from which the reconquest of Portugal from the Moors was carried on. Six kings—Sancho I and II, Afonso II and III, Pedro and Ferdinand—were born there, as was the poet Francisco de Sá de Miranda (1481-1558). In 1755 Coimbra suffered considerably from an earthquake and in 1810 it was sacked by the French. Dom Miguel made the city his headquarters in 1834 and in 1846 it was the scene of a Miguelist insurrection. (M. C. CA.; A. C. DA S.)

**COIN:** see MINT; NUMISMATICS.

**COINAGE OFFENSES:** see COUNTERFEIT MONEY.

**COIR** is the fibre obtained from the shell of the coconut. It can be processed by machinery but is considered to be of superior quality when processed by hand. After steeping in sea water, washing in fresh water and drying, the reddish-brown mass of fibre is opened up into fibres five to ten inches long, which are graded according to the end use. Coir is employed extensively in rope, brush and mat manufacture. It is resistant to rot, and its other valuable features include lightness coupled with elasticity and resistance to mechanical wear and abrasion. Considerable quantities are exported from the Pacific, and cultivation and preparation of coir also play a major part in Ceylon's economy. Great Britain imports substantial quantities of coir, largely for re-export after manufacture. The Federal Republic of Germany, the Netherlands, the United States, France and Italy also import and manufacture considerable amounts. (A. DR.)

**COITER** (COYTER, KOYTER), **VOLCHER** (1534-1590?), Dutch physician and surgeon who established the study of comparative osteology and first described cerebrospinal meningitis, was born in Groningen, in the Netherlands. He was awarded a grant by his native city that enabled him to study for five years at the principal universities of Italy and France under such masters as Fallopius, Eustachius, Aranzi and Rondelet. In 1569 he was appointed city physician of Nürnberg. Shortly afterward he entered military service as field surgeon to the palatine prince Johann Casimir. The time of his death is variously given, ranging from 1576 to 1600.

Coiter was a brilliant investigator whose interests covered the full range of the medical sciences of his time. He corrected some of the errors of Vesalius, and concerned himself with the finer

structures of the sense organs and the nervous system. He described embryology, particularly the development of the human fetus, as well as the comparative osteology of animals and illustrated the descriptions with his own drawings. He performed human autopsies whenever the opportunity presented, and described many disease processes, including cerebrospinal meningitis (1573). (L. M. Z.)

**COJEDES** in northern Venezuela is regarded as one of the most typical llanos (grassland) states. Area 5,714 sq.mi., pop. (1961) 72,181. Since colonial days cattle raising has completely dominated the economy. The area is drained by secondary tributaries of the Orinoco. The climate is wet and dry tropical with about 48 in. of rain falling during the rainy season (May to September or October). Rains bring much hardship to the *llaneros* ("cattlemen"). In the capital, San Carlos, the temperature ranges between 63° F. in the rainy season and 102° F. in the dry season. No point in Cojedes rises above 700 ft. Coffee is grown in the hills to the north and corn, cotton, sugar cane and yuca (cassava) to the south where irrigation is possible. San Carlos and Tinaquillo are the principal market centres. (L. Wæ.)

**COKE, SIR EDWARD** (1552-1634), English lawyer and parliamentarian whose defense of the supremacy of the common law against the claims of the royal prerogative had a profound influence on the development of English law and the constitution, was born at Mileham in Norfolk on Feb. 1, 1552. He was educated at Norwich grammar school and Trinity college, Cambridge, and entered the Inner Temple in 1572. Called to the bar in 1578, he soon acquired a reputation, his early cases including the Cromwell libel case (4 Rep. 13) and *Shelley's Case* (1 Rep. 94). Under the patronage of Lord Burghley, Elizabeth I's first minister, he entered the public service and rose rapidly, becoming member of parliament for Aldeburgh in 1589 and solicitor general and recorder of London in 1592. A year later he was elected speaker of the house of commons, showing considerable skill in carrying out Queen Elizabeth's policy of curbing the commons' passion for discussing ecclesiastical matters. In 1593 he first crossed the path of Francis Bacon (*q.v.*). The attorney generalship fell vacant, and Bacon, supported by the earl of Essex, became Coke's rival for the post. Coke got it in 1594 and then kept Bacon out of the office of solicitor general as well, or so Bacon thought. Coke's first wife, Bridget Paston, died in 1598 and four months later Bacon was again his unsuccessful rival when he married Lady Elizabeth Hatton; it was a tempestuous and unhappy union.

As attorney general Coke was the champion of the crown and its prerogative powers. He started a series of state prosecutions for libel and conducted the great treason trials of the day, prosecuting the earls of Essex and Southampton in 1601, Sir Walter Raleigh in 1603 and the Gunpowder plot conspirators in 1605. His methods in these trials, especially in that of Raleigh, were brutal even by the standards of his age.

In 1606 Coke was made chief justice of the common pleas, and there then began the series of conflicts which eventually broke his judicial career. At the time of Coke's appointment Archbishop Richard Bancroft had already started his attempt to shake off the control which the common-law courts exercised over the ecclesiastical courts by writ of prohibition. This matter came to a head in *Fuller's Case* (1607-08) when Coke, summoned to a disputation on the king's power to withdraw a case from the courts, earned James I's fury by his assertions that the common law was the supreme law and that "the king in his own person cannot adjudge any case. . . ." In 1610 Coke again crossed the king when he gave his celebrated opinion on proclamations before the council, stating that the king cannot change any part of the common law nor create any offense by proclamation which was not an offense before. The same year he disputed the claim of the court of high commission to imprison for adultery and when, in 1611, James attempted to put him on the commission he refused.

Coke's position was strong. Incorruptible and respected, he was the embodiment of the common law. A last attempt was made to "buy" him when in Aug. 1613 James, on Bacon's advice, appointed him chief justice of the king's bench where it was hoped he would look after the royal interests. He was also made a privy

councilor and was the first to be called lord chief justice of England. At the king's bench he retained his predominance and continued to maintain the supremacy of the common law over all persons and institutions except parliament. In *Peacham's Case* he protested against the practice of consulting the judges individually and separately, which James, abetted by Bacon, was more or less driven to follow when the whole bench, if consulted together, merely echoed Coke. In 1615, however, he tried his strength too high, for the court of king's bench started a dispute with Lord Chancellor Ellesmere (*see* BRACKLEY, THOMAS EGERTON) over the right of the court of chancery to interfere with, and indirectly nullify, a common-law decision. Coke was also believed to be at the bottom of the abortive attempt to make some who had been suitors in a case of this sort liable to the penalties of a praemunire. Meanwhile he had further endangered his position by throwing out from the bench in the Overbury murder trials dark hints of scandal in high places ("God knows what became of that sweet babe, Prince Henry, but I know somewhat"). Finally he came into collision with James I over the king's right to grant commendams (permission to hold livings in plurality). Coke and the other judges ignored a royal injunction that they should take no action upon a case involving this right until the king's pleasure was known. They were called before the king and council and ordered to obey the injunction. The other judges submitted, but Coke merely said that he would do what an honest and just judge ought to do.

In June 1616 the privy council, with Bacon behind it, formulated three charges against him. One was a trumped-up matter, never proved, about a bond that had passed through his hands. The other two were charges of interference with the court of chancery and of disrespect to the king in the matter of commendams. Coke was forbidden to go on circuit, ordered to revise the "errors" in his *Reports* and on Nov. 14, 1616, he was dismissed. Thereupon, presumably in search of an influential friend, he offered his daughter in marriage to Sir John Villiers, brother of the duke of Buckingham. His wife, supported by Bacon, objected and hid the child, who was then only 14. Coke abducted her violently and had her married, strongly against her will, to Villiers. Coke made a gradual return to public life, and by 1617 was back in the privy council and in the Star Chamber.

In 1620 Coke entered parliament again as member for a Cornish borough, in theory as a supporter of the king. Yet for the rest of his career he was a leading member of the popular party. He opposed Prince Charles's proposed Spanish marriage, took a part in drawing up the charges against Bacon and spoke in the great debate on the liberties of parliament (1621), spending nine months in prison as a result, but nothing was found that could incriminate him. In 1628 it was his bill of liberties that ultimately took the form of the Petition of Right. This was his greatest parliamentary hour. Admitting his changed views, Coke, at the age of 76, molded the ancient precedents, including Magna Carta, into a charter of liberty limiting the royal prerogative. He retired at the end of the session and died at Stoke Poges, Buckinghamshire, on Sept. 3, 1634. His papers were instantly seized and some, including his will, were never recovered.

It is true that Coke was inclined to be overbearing and impatient both at the bar and on the bench, that he was undoubtedly rather narrow and that he was not always logical. However, his knowledge of law was unequaled, though he "read the Year Books as a Tudor, not as a medieval lawyer." Coke manipulated medieval "precedents" and used them to support his 17th-century view of the common law. He successfully upheld this common law in the courts and in parliament, against the church, the admiralty and the dangerous claims of the royal prerogative. He only failed in trying to uphold it against the chancery, which was too strong for him. While he was issuing his *Reports* no others came out. They are not so much reports in the modern sense as compendiums of the law bearing on a particular case, with personal comments on points raised or general remarks. A balanced estimate of his importance as a legal authority is that of Chief Justice William Best: "The fact is that Lord Coke had [often] no authority for what he states, but I am afraid we should get rid of a great

deal of what is considered law in Westminster Hall if what Lord Coke says without authority is not law. He was one of the most eminent lawyers that every presided as a judge in any court of Justice. . . ." Among his other publications are four volumes of *Institutes*, of which vol. i is known as *Coke Upon Littleton* (1628).

As a man, he evokes admiration more readily than sympathy. More learned a lawyer than Bacon but without his philosophical genius, proud, ambitious and domineering, a just judge but a savage prosecutor, obstinate in his opposition to illegal exercise of authority, resolute in his faith in the supremacy of the common law even to the extent of challenging the equity of the chancellor, he could cringe before the king even in the act of defying the crown.

**COKE, SIR JOHN** (1563-1644), English royalist, who gave valuable service to Charles I, especially during the "11 years' tyranny," was born on March 5, 1563, and was educated at Trinity college, Cambridge. After leaving the university he entered public life as a servant of William Cecil, Lord Burghley, becoming deputy treasurer and then a commissioner of the navy. He became M. P. for Warwick in 1621 and was knighted in 1624, afterward representing the University of Cambridge. In the parliament of 1625 Coke acted as secretary of state (he was permanently appointed in Sept. 1625). In this and later parliaments he introduced the royal requests for money and defended the foreign policy of Charles I and other actions of the king. Disliked by the leaders in the house of commons, his speeches did not improve the king's position, but when Charles ruled without a parliament he found Coke's industry very useful. However, in 1639, when a scapegoat was required for the humiliating treaty of Berwick with the Scots, Coke was dismissed. He died at Tottenham on Sept. 8, 1644. Coke's son, Sir John Coke, sided with the parliament in its struggle with the king, and it is possible that in later life Coke's own sympathies were with this party, although in his earlier years he had been a defender of absolute monarchy. (S. R. Br.)

**COKE, THOMAS** (1747-1814), the first Methodist bishop and founder of Methodist missions, was born at Brecon, Wales, on Sept. 9, 1747. He was educated at Jesus college, Oxford, and ordained in the Church of England in 1772. From 1772 to 1776 he was curate at South Petherton in Somerset, but he was dismissed for adopting the open-air and cottage services suggested by John Wesley, with whom he had become acquainted. After serving on the London Wesleyan circuit he was in 1782 appointed president of the first conference in Ireland. In 1784 he presented to Wesley his *Plan for Missions* and on Sept. 2 he was ordained by him as "superintendent" of the Methodist societies in the new world and left on the first of his many visits to America. In 1787 the American conference changed his title to "bishop," a nomenclature which he tried in vain to introduce into the English conference, of which he was president in 1797 and 1805. Failing this, he asked the prime minister, Lord Liverpool, to make him a bishop in India. Refused, he raised funds to establish his own mission and was on his way there when he died at sea on May 3, 1814. Coke was always a missionary enthusiast, and the pioneer of such enterprise within the Methodist movement. He was an ardent opponent of slavery, and endeavoured also to heal the breach between the Methodist and Anglican communions. He published a *History of the West Indies* (1808-11), several volumes of sermons and, with Henry Moore, a *Life of John Wesley* (1792).

**COKE, COKING AND HIGH-TEMPERATURE CARBONIZATION.** Coke is the solid residue which remains when certain types of bituminous coals are heated to a high temperature out of contact with air until practically all of the volatile matter has been driven off. The residue consists principally of carbon, with minor proportions of hydrogen, nitrogen, sulfur and oxygen (which together constitute the so-called fixed carbon), plus the mineral matter present in the original coal, which has undergone alteration during the coking process.

The process of heating bituminous coal in this manner is referred to as carbonization or coking. The properties of coke depend on

the type of coal or coal mixture from which it is made and the process and temperature used in its manufacture. In high-temperature carbonization, with which this article is concerned, the final temperature of the coke discharged from the ovens is about 900° C. (1,652° F.) or slightly higher. The primary purpose usually is to produce a coke having the requisite properties for metallurgical use, as in blast furnaces or in foundry cupolas, although the gas, tar and light oils recovered are also valuable products. In Great Britain and Europe, but no longer in the United States because of the availability of natural gas, processes of carbonization employing special retorts are used for the primary purpose of making city gas (coal gas), with coke production a secondary objective. Such processes produce a coke suitable for varied industrial, commercial and residential uses, but not the type required for blast furnaces and foundry cupolas. (The making of coal gas is described in GAS INDUSTRY; see also FUELS: *Gaseous Fuels: Coal Gas*.) Coal carbonization may also be accomplished at lower temperatures of about 500° to 600° C. (932°-1,112° F.). The coke is higher in volatile-matter content, is much more reactive and therefore suitable for use in residential heating equipment, but is not of metallurgical quality. (See CARBONIZATION, LOW-TEMPERATURE.)

### THE NATURE OF COKE

Coke is a hard, cellular mass of carbonaceous material ranging in colour from silvery gray to a dull black. Oven coke is of irregular shape and size, with the maximum dimension of from six to ten inches, which is one-half the width of an oven. Coke made in beehive ovens occurs in blocks or columns of irregular length, which may be as long as two feet, depending upon the depth to which coal has been charged on the floor of the oven. Beehive coke is more silvery and uniform in appearance than oven coke. The end of a piece of oven coke which has been at the wall of the oven has a cauliflower appearance, a more silvery colour, and has been more thoroughly coked than the end at the centre of the oven. Wide differences in size, appearance, colour, hardness, porosity and other properties are shown by cokes from different sources. These differences result for various reasons including the oven wall temperature, coking time, type of coal mixture, and other material and operating factors.

Coke is essentially a partially graphitized and cellular form of carbon; its true specific gravity is about 1.85 to 1.9, or about midway between the specific gravities of coal and graphite. Because of its cellular structure and high porosity, however, coke has a lower bulk density than coal; that is, coke requires about 40% more storage space than an equal weight of coal. It is the combination of high graphitization and porosity that gives coke its chief value in the smelting of iron. For this purpose a fuel is required which will burn rapidly in the lower regions of the blast furnace, furnishing a high temperature for the melting of the iron and slag. Also required is a high mechanical strength to withstand rough treatment. Resistance to reaction with carbon dioxide in the higher levels of the furnace is also required.

The undesired constituents of coke are mineral matter (evidenced by the ash content), excessive moisture, volatile matter, sulfur and phosphorus. Except for the moisture, these are constituents which were part of the coal charged to the ovens, although in altered form because of the treatment at high temperatures. Reduction of these constituents in the coke is a problem of coal selection, cleaning and preparation. Sulfur and phosphorus are undesirable in metallurgical coke because they enter into the iron and must be removed when the iron is converted into steel.

### HISTORY OF COKE MAKING

The early history of the manufacture and use of coke made from coal for the smelting of iron ore is somewhat obscure. Because of the ravages caused in timber supplies by the expansion of the charcoal-using iron industry in England during the 16th century, a number of acts of parliament were passed in the last half of the century severely restricting the number and location of iron-works. The attention of ironmasters was thus directed to the desirability of finding substitute fuels, and a number of patents

were granted from 1589 onward covering the use of coal for the manufacture of iron. In spite of the granting of patents, these early attempts to smelt iron ore using coal or coke were unsuccessful in practice. In many instances it is impossible to discover whether coke or the raw coal was used. In 1621, Lord Dudley was granted a patent on a process developed by his son, Dud Dudley, who, in his *Metallum Martis* (1665) put forward exaggerated claims that the iron produced was superior to that smelted and refined by charcoal. It is doubtful whether it would have been possible to produce iron of acceptable quality with raw coal in the equipment and plant available at that time but the use of coke is not mentioned. The first recognized success in the substitution of coke made from coal for wood charcoal in the smelting of iron was the result of the persistent efforts of the Abraham Darbys, father and son, of Shropshire, Eng., during the early 1700s.

As might be expected, the early process for the manufacture of coke closely followed that applied to the production of wood charcoal (*q.v.*). The coal was built up in piles and set on fire, care being taken that only part of the coal was burned; the remainder carbonized to form coke. The method was exceedingly wasteful; yields were low, gas and tar were lost, and it was impossible to secure uniform carbonization. Later, some control of the process was obtained by building the pile around a brick chimney with gaps in it through which gases could enter. This was closed at the top, when necessary, by a damper. A still later development was to carry out the carbonization in long piles enclosed by two brick walls provided with holes for the controlled admission of air.

By about 1850 the beehive process had almost completely displaced the foregoing. In this process, small charges of coal were coked by the heat released from combustion of practically all the volatile matter and about one-sixth of the theoretical yield of coke. The ovens used were round in shape with domed roofs and were constructed of firebrick and stone. Although still highly inefficient, the beehive process produced excellent coke from coals having strong coking properties. Various improvements in the beehive oven were introduced in the last half of the 1800s, but those still in use are relatively unchanged in their principal features of construction.

Fig. 1 is a cross-sectional view of a standard beehive oven showing a residue of coke before removal. Coal is charged to the floor of the oven through an opening in the roof and is leveled through the opening in the side. Heat remaining in the brickwork from the previous run starts the distillation of volatile matter. Air admitted at the top of the side door mixes with the volatile matter and combustion occurs chiefly above the coal charge. The progress of coking is downward. It is important that the air admitted be controlled to avoid loss of coke, and the amount of air admitted is reduced as coking proceeds. From five to six tons of coal are charged to an oven, and the time of coking may run from 48 to 73 hours, depending upon the type of coal charged and the coke properties desired.

In the operation of a beehive oven all of the gaseous and liquid chemical products, which represent about 40% of the heat content of the coal charged, are lost. Numerous efforts were made in the last half of the 1800s to reduce this heat loss and to recover tar,

ammonia and surplus gas. Waste heat boilers were added to the beehive oven to aid in heat recovery from the combustion products. Improved ovens, rectangular in cross-section, were devised, with separate flues on the sides for combustion of the volatile gases liberated and transmission of heat to the charge through the walls of the oven. By-product recovery systems were added and provision was made to remove tars and light oils from the raw gas before it was directed to the heating flues. An important advance was made when Henry Simon, of Manchester, Eng., introduced a recuperative system whereby part of the heat of the burned gases from the heating flues was used to preheat the air which was supplied to the flues. As a result higher temperatures were obtainable in the ovens, and some surplus gas became available.

During these developmental years, ovens were narrowed to furnish coke of more uniform properties, and heating flues were redesigned to give more uniform heating throughout the length of the oven. More elaborate systems for recovery of chemical products were devised. The names of Simon-Carvès, Coppée, Piette, Otto, Semet-Solvay, Koppers, and Wilputte, who were coke oven designers and builders, are still familiar to coke-oven operators.

The first by-product coke ovens built in the United States were installed in 1893 at the plant of the Solvay Process company, Syracuse, N.Y. These were designed by Louis Semet and their primary purpose was to produce ammonia for use in the Solvay ammonia-soda process. The coke and gas obtained were used as fuels. Within the next few years, the quality of coke produced in by-product ovens was demonstrated to the satisfaction of blast-furnace operators and other oven installations were made by Semet-Solvay, Otto-Hoffman and others. Ovens designed by Heinrich Koppers, of Germany, were installed in 1906 at the plant of the Illinois Steel company, Joliet, Ill. The first real impetus to coke oven construction resulted from demands for ammonia, benzene and toluene for explosives and tars for dyes during World War I when imports of these coal-derived chemical products from Germany ceased. By 1919 more coke was produced in the United States from by-product ovens than from beehive ovens, and ten years later over 90% of the coke was produced in the new ovens. For many years beehive ovens have been operated chiefly to supply peak demands for metallurgical coke.

### THE COKE-OVEN PLANT

The modern coke-oven plant consists of an area for receiving coal by rail or barge, with provision for handling, storage, blending and handling several types of coal, one or more batteries of coke ovens, a plant for recovery of the gas and chemical products, and equipment for the discharge and quenching of the coke and for screening the coke and delivering it to storage, rail cars or the blast furnace. All operations are integrated and continuous.

**Chemical-Recovery Coke Ovens.**—In the United States the term by-product was being replaced in the second half of the 20th century by the term coal chemicals, and the coke ovens from which coal chemicals are recovered were being referred to as chemical-recovery coke ovens. A typical modern chemical-recovery coke oven in the United States and other countries is a rectangular chamber constructed of refractory materials. Each oven is about 40 ft. long and 12 to 13 ft. high, with an average width of 17 to 20 in. The width is tapered 2 to 4 in. from front to back, with the wider dimension at the back to facilitate discharge of the coke by a pusher. For convenience in operation, a group of about 50 or 60 ovens are built closely side by side in a single structure known as a battery.

Rows of heating flues separate the ovens, each row serving to heat two ovens except for the flues at each end of the battery. The flues connect into the regenerators which are located immediately below each oven and which supply preheated air for combustion and receive the hot products of combustion. The heating gas is directed into the flues by a separate duct when the ovens are heated with coke-oven gas. Many of the coke ovens of the combination type are designed to be heated with either coke-oven gas or blast-furnace gas (also producer gas) in which case the blast-furnace gas (or producer gas) as well as the air is preheated in regenerators. Heating is carried out in half the number of flues

BY COURTESY OF U.S. BUREAU OF MINES, DEPARTMENT OF THE INTERIOR

FIG. 1.—CROSS SECTION THROUGH A BEEHIVE COKE OVEN

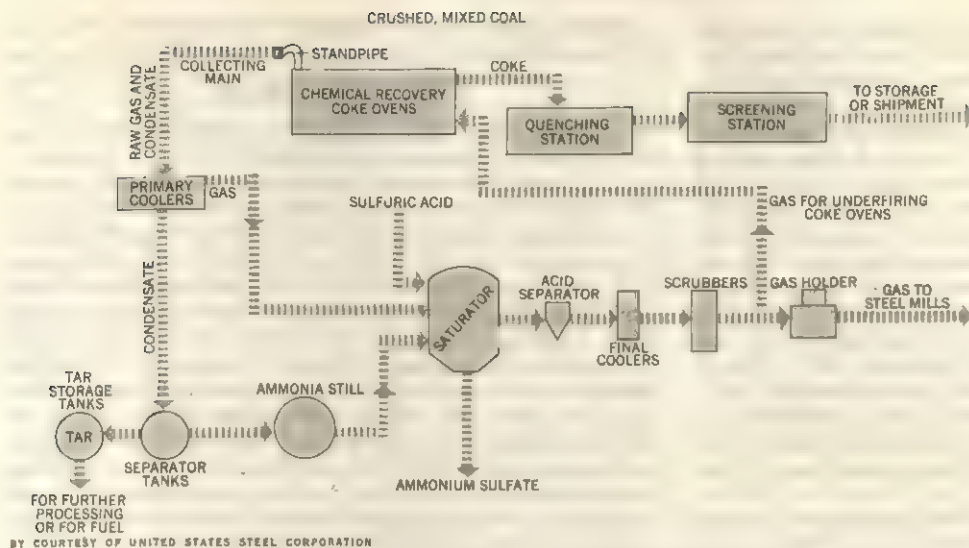

FIG. 2.—FLOW SHEET SHOWING THE OPERATION OF COKE AND COKE CHEMICALS PRODUCTION

for 20 to 30 minutes; then the system is reversed and heating is carried out in the other half. The oven structure is built almost entirely of silica brick. This refractory, because of its rigidity under load, permits the use of higher temperatures in the flues and thus secures more rapid working and greater oven capacity than is attainable with fire-clay brick. Flue temperatures of 1,370° to 1,455° C. (2,500° to 2,650° F.) are commonly used in modern U.S. ovens, but temperatures vary depending on the rate of production or quality of coke required.

A popular type of chemical-recovery oven in the United States is the Becker modification of the Koppers oven, the distinguishing feature of which is its provision for conducting the gases of combustion from the top of a row of vertical flues across and over the oven and down the row of flues on the other side (see fig. 2). The crossover flues, of an inverted-U shape, are in the upper part of the oven battery structure. They pass over alternate ovens only, and are usually six to eight in number, distributed across the length of the oven. Each crossover flue handles the waste gases from four to six vertical flues in the heating walls beneath, and each set of vertical flues is separated from each other set. The heating gases burn in all of the flues in one-half of the number of walls, and when reversal takes place for the purpose of regeneration the heating gases burn in the remaining half. This procedure is in contrast with the system where heating gases burn in one-half of the flues in each wall on each reversal. This construction and flow pattern results in more uniform heating, end to end, of the oven walls, and a stronger flue and oven structure.

**Operation of Coke Ovens.**—Modern chemical-recovery coke ovens have a capacity of from 15 to 20 net tons of finely crushed coal having a bulk density of about 50 lb. per cubic foot in the oven. At normal rates of operation, each oven has a daily capacity of about 20 to 24 tons of coal. Coal is charged into the hot ovens from a car that runs on top of the ovens and is filled from central mixing bins. Before being charged, doors at each end of the oven are closed and sealed. After the charge is dropped in the oven, the top of the coal is leveled, the lids on the charging doors are closed, and the volatile gases which have started to evolve are directed into the collecting main. The charging and leveling operation is done rapidly, usually requiring only 1½ to 2 minutes. The time required to carbonize the coal is dependent chiefly upon the width of the oven and the temperature of the adjacent flues. At normal rates of operation the coking time is about one hour for each inch of oven width. When foundry coke is being made the period is slightly longer. At the end of the coking period, the oven doors are removed and the hot coke, at a temperature of about 980° C. (1,800° F.), is pushed mechanically into a car at the rear of the furnace. To prevent loss by combustion in the air, the incandescent coke in the car is taken immediately to a quenching station at one end of the battery where it is cooled with a controlled amount of water. A dry quenching process to recover

the sensible heat of the hot coke is sometimes used. The quenched coke is dumped on an inclined wharf where it cools further and is then transported by belt conveyor to a screening station and separated into sizes before storage or shipment.

#### Recovery of Coal Chemicals.

—Methods for the recovery of coal chemicals from the raw gas leaving the coke ovens vary somewhat according to the way the ammonia is recovered. Three methods have been used—the so-called direct, semidirect and indirect processes. Ammonia is recovered as ammonium sulfate in the direct and semidirect processes. A dilute ammonia liquor is produced in the indirect process. Ammonia stripped from this

liquor is either converted to ammonium sulfate or concentrated in solution. The direct process is not used in the United States and seldom is used in Europe. The great majority of plants in the United States employ the semidirect process with production of ammonium sulfate.

In the recovery of coal chemicals, the volatile products leaving the ovens enter a standpipe leading to a collecting main where the gas is first cooled and initial condensation of the tar takes place. After the gas is further cooled in the primary coolers and more tar is extracted, the ammonia is recovered by the semidirect process in which the gases are passed through a weak solution of sulfuric acid either in specially designed low-differential saturators or spray-type ammonia absorbers. The ammonia is thus converted into solid, crystalline ammonium sulfate. Light oil containing benzene, toluene, xylenes and higher boiling hydrocarbons is scrubbed from the gas by a petroleum-type absorbent oil after which the light oil is steam distilled from the scrubbing oil. The gas, which has a heating value of about 530 B.T.U. per cubic foot, requires no further treatment when used for underfiring the ovens or in the steel-mill furnaces, but removal of hydrogen sulfide and naphthalene is necessary for distribution in city mains.

The approximate average yields of products obtained from the carbonization of 2,000 lb. of coal in the United States is as follows:

Coke, total, including breeze, lb.	1,410.00
Tar, gal.	8.32
Ammonium sulfate or equivalent, lb.	19.56
Crude light oils, gal.	2.94
Gas, total, cu.ft.	10,400.00

Of the total gas produced about one-third is used to underfire coke ovens, and almost two-thirds is sold to gas utility systems or used in associated steel plants and allied industries. Only a small proportion, about 5%, of the coke oven gas produced is sold for distribution in city mains. In the years up to 1946 as much as 20% was used for this purpose. The availability of relatively inexpensive natural gas by pipeline in virtually all areas of the United States has led to a rapid conversion of city distribution systems from manufactured and coke-oven gas to natural gas.

Mention of the broad categories of coal chemicals produced by carbonization—tar, light oils and gas—gives no hint of the hundreds of important chemicals, pharmaceutical and industrial compounds, dyestuffs and explosives derived from these basic materials. The organic chemical products obtained from coal by carbonization constitute an indispensable source of materials for the chemical industry. (See COAL AND COAL MINING: Preparation and Uses of Coal: By-products of Coal).

#### UTILIZATION OF COKE

Coke is designated by its method of manufacture, such as oven coke, beehive coke or retort coke. It is also designated by the use to which it is put, as blast-furnace coke (or simply furnace

coke), foundry coke, water-gas coke, or domestic coke (for house heating). Another method of designation, chiefly applied to domestic coke, is by size. The usual size classification is egg (largest), stove, nut, range, pea and breeze.

Of the total coke produced in the United States, about 94% is used in metallurgical processes—91% in blast furnaces and 3% in foundries. The remainder of the coke is used as follows: 1% for producer-gas and water-gas manufacture; 1% for residential heating; 1% for export and 3% for various industrial purposes. In the late 1930s as much as 23% of the coke produced was used for residential heating, but this market rapidly disappeared as natural gas became widely available following World War II. A notable improvement in fuel efficiency was achieved by the iron and steel industry during the decade ending in 1957. Whereas an average of 1,937 lb. of coke were required to produce a ton of metal (pig iron and ferroalloys) in 1948, only 1,703 lb. were required in 1957. Contributing to this reduction in coke requirements were improvements in iron ore preparation, blast furnace operation and coke quality.

**Qualities of Metallurgical Coke.**—Assessment of the quality of metallurgical coke other than by full-scale use involves consideration of chemical and physical properties which can be determined by standard laboratory tests. Those of a chemical nature apply chiefly to quantitative analytical determinations involving impurities (moisture, sulfur, ash and phosphorus). Because coke is the chief source in pig iron of sulfur, an undesirable constituent, the sulfur content should be low, preferably 1% or less. The phosphorus content should also be low, 0.01% to 0.02%, especially for the production of bessemer and basic open-hearth metal. Over the years cokes ranging in ash content from 8% to 16% have been used in blast furnaces but a good coke should not contain more than 12%. Under most conditions, higher rates of iron production are obtained when the ash content is low. A good coke contains no more than 2% volatile matter, and the moisture content should not exceed about 5%. Above all, uniformity is essential, with elimination of day-to-day variations.

Physical and strength qualities are even more important. Strength to resist breakage is demanded since from the time coke is pushed from the oven to the time it is dropped on the stock line of the blast furnace or cupola it is subjected to impact and abrasion by falls and slides on wharfs, conveyers, screens, weighing hoppers and crossbelts. Within the furnace it must resist the abrasive action of walls and the other charge materials and, in the lower layers of the charge, it must have sufficient strength to withstand the heavy weight of the materials above it at the prevailing high temperatures. Standard tests are designed to evaluate coke strength by carefully defined impact and abrasive actions in laboratory-scale equipment. Size is an important criterion, particularly uniformity of size. A maximum size of about 4 in. is desirable for blast-furnace use, with exclusion of fines smaller than about  $\frac{3}{4}$  in. which would otherwise fill up voids in the charge and interfere with the uniform upward flow of gases throughout the cross section. Better results are obtained by charging separately the smaller sizes of coke, about  $\frac{3}{4}$  in. by 2 in., rather than including these sizes with the larger pieces.

No common agreement exists on what constitutes the optimum quality of metallurgical coke. Coke suitable for one furnace and the corresponding operating conditions may not be suitable for others. Discussion of coke quality can be controversial because of substantial differences between blast furnaces, types of burden and conditions of operation. Most of the physical tests are empirical in nature, and the results, to be significant, must be correlated with experience in practice. Attempts have been made to formulate an over-all index of quality for evaluating and correlating coke properties with blast furnace operation. Several have been developed by individual iron and steel companies and used with some success, but agreement on a single formula has not been reached.

Operators of foundry cupolas require a coke that is large in size, dense in structure, with small cells and thick cell walls, and having high values for strength, hardness, heating value and carbon content. Again, the coke should be low in moisture, ash,

volatile matter, sulfur and phosphorus. The reactivity of the coke with carbon dioxide to produce carbon monoxide should be low.

## COALS FOR COKING

Only coals of bituminous rank produce a coke of suitable properties, and not all bituminous coals are able to do so. Some contain too many impurities such as ash and sulfur. In this respect, many otherwise suitable coking coals can be upgraded by commercial cleaning processes. In the process of being transformed by heating into coke, the coal passes through a fusion or plastic stage with some fusible components becoming softened, other components becoming vaporized and still others, thermally less stable, becoming decomposed. As a result, gases are evolved with the formation of small gas-filled cells in the plastic mass and the process continues until solidification occurs and a rigid cellular structure is maintained. When and how these interacting processes occur under the time-temperature conditions prevailing determines the yield and quality of the coke and the attending tars and gases. Variations in cellular structure, fracture and strength result with different coals. Some coals build up internal pressures that result in heavy pressures being exerted on the walls of the oven.

Because it is difficult to find a single coal having all the requisite properties, it is general practice to blend two or more coals into a mix which will perform satisfactorily in the oven and produce a quality coke. For example, some high-volatile coals are highly fusible and tend to produce a frothy coke of low strength. Coals of low-volatile matter content exert high pressures against the walls of the oven with the attendant possibility of damage to the refractory structure. By blending these coals in suitable proportions (70% to 85% high-volatile type, 15% to 30% low-volatile types), the quality of the coke can be improved and the danger of excessive pressure minimized. Blending also furnishes an opportunity to include less desirable but locally available low-cost coals and still produce a satisfactory coke.

Because of the varied qualities and coking propensities of coals, it has been necessary to devise laboratory tests to give preliminary evaluation of their probable behaviour in commercial ovens. In addition to the usual analytical tests for ash, sulfur, moisture and volatile matter, empirical physical tests have been developed to assess such properties as plasticity and expansion pressure. Moisture content, bulk density, degree of fineness and size distribution, and petrographic composition of the coals used also affect the resultant properties and quality of the coke. Pilot-scale test ovens and related facilities for carbonization research have been developed in several countries.

To a limited extent it is possible to enhance the quality of coke made from marginal coals by methods involving adjustment of particle size by such procedures as grinding, changing the bulk density of charged blends by tamping or compressing the charge as it is placed in the oven, concentration of petrographic constituents, or addition of pitch or similar substances to the blend.

Although coal is widely distributed throughout the world, the reserves of good coking coals are limited and many countries are without adequate supplies and must import all or a portion of the coals used for coking operations.

**COKE OF NORFOLK:** see LEICESTER OF HOLKHAM, THOMAS WILLIAM COKE, EARL OF.

**COLBERT, JEAN BAPTISTE** (1619–1683), French statesman and minister of finance to Louis XIV, was born on Aug. 29, 1619, at Reims, where his father, son of a merchant and a merchant himself, had already bought some official appointments. In 1651, when Cardinal Mazarin had to leave Paris during the Fronde, Colbert became his agent there. He kept the cardinal abreast of the news and looked after his personal affairs. Mazarin,

on his return to power, made Colbert his intendant and helped him purchase profitable appointments for his family and for himself. Quickly enriched, Colbert also acquired the barony of Seignelay, which was subsequently raised to a marquise for him. On his deathbed, Mazarin recommended him to Louis XIV, who soon gave Colbert his confidence. Thenceforth Colbert dedicated his enormous capacity for work to serving the king both in his private affairs and in the general administration of the kingdom.

**Financial and Economic Affairs.**—For 25 years Colbert was to be concerned with the economic reconstruction of France. The first necessity was to bring order into the chaotic methods of financial administration. He caused the fall of the all-powerful *surintendant des finances*, Nicolas Fouquet (*q.v.*), who had rendered great services to the state by using his personal credit, but who made no distinction between his own fortune and public money. Fouquet's trial (1661–64), mysterious in many ways, was conducted without equity, and pressure was brought to bear on his judges. The *surintendance* was replaced by a council of finance, of which Colbert was to be the dominant member, with the title of intendant until, in 1665, he became controller general.

Financiers and tax farmers had made enormous profits from loans and advances to the state treasury, and Colbert established tribunals (*chambres de justice*) to make them give back some of their gains. Well received by public opinion, which held the financiers responsible for all difficulties, these measures alleviated the public debt, which was further reduced by the repudiation of some government bonds and the cancellation of others by paying back the principal less the interest already paid. Many private fortunes suffered, but no disturbances ensued, and the king's credit was restored. Colbert would have liked to avoid further public borrowing but was obliged to have recourse to loans during the Dutch War of 1672–79. On the conclusion of peace, loans at advantageous rates of interest helped cancel old debts.

France under the monarchy was divided between (1) *pays d'états*, where the representatives of the province voted the tax; and (2) *pays d'élection*, which paid the *taille* (*q.v.*), a distributory tax levied only on *roturiers*. Colbert intended to levy the *taille* on all who were properly liable for it and so initiated a review of titles of nobility in order to expose all those who were claiming exemption falsely, but he also wanted to make the tax less oppressive by a fairer distribution. He reduced the total amount of it but insisted on payment in full over a reasonable period of time. Furthermore, he took care to suppress many abuses of collection (confiscation of defaulters' property, seizure of peasants' livestock or bedding, imprisonment of collectors who had not been able to produce the due sums in time). These reforms and the close supervision of the officials concerned brought large sums into the treasury. Indirect taxes moreover were increased, and the tariff system was revised in 1664 as part of a system of protection. The special dues which existed in the various provinces could not be swept away, but a measure of uniformity was obtained in central France.

Colbert sought to organize industry and commerce on the principles of mercantilism, according to which a country could not prosper unless it exported much and imported little, thus increasing its gold reserve. This necessitated not only the production of high-quality goods which could compete with foreign products abroad but also the building up of a merchant fleet to carry them. Colbert attracted foreign workers who brought their trade skills to France. He gave privileges to a number of private industries and founded state manufactures. To guarantee the standard of workmanship, he made regulations for every sort of manufacture and imposed severe punishments (fines and the pillory) for counterfeiting and shortcomings. He encouraged the formation of companies to build ships and tried to obtain monopolies for French commerce abroad through the formation of trading companies. The French East India and West India companies, founded in 1664, were followed by others for trade with the eastern Mediterranean and with northern Europe, but Colbert's propaganda for them, though cleverly conducted, failed to attract sufficient capital, and their existence was precarious. The protection of national industry demanded tariffs against foreign produce, and

other countries replied with tariffs against French goods. This tariff warfare was one of the chief causes of the Dutch War.

Colbert's system of control was resented by traders and contractors who wanted to preserve their freedom of action and to be responsible to themselves alone. Cautious and thrifty people, moreover, still preferred the old ways of placing their money (land, annuities, moneylending) to investing in industry. The period, too, was one of generally falling prices throughout the world. Colbert's success, therefore, fell short of his expectation, but what he did achieve seems all the greater in view of the obstacles in his way: he raised the output of manufactures, expanded trade, set up new permanent industries and developed communications by road and water across France (Canal du Midi, 1666–81). He ensured progress in every sphere of the economy.

**The Navy.**—As secretary of state for the navy from 1668, Colbert undertook to revive the power of France at sea. This meant forming a fighting fleet, building and equipping the king's ships, fortifying ports and encouraging the merchant navy. The Atlantic fleet was composed of sailing ships, the Mediterranean fleet of galleys. To man the Atlantic fleet the system of *inscription maritime* and of *classes* was devised: under this, professional sailors were required to sign on for the king's service so that crews of 300 men could be formed; they were then divided into *classes*, which served in rotation. Those not called up were free to serve in the merchant navy. They received half pay when they were not serving, their families received their pay when they were serving overseas, their children had free education and pensions were provided. Ill-received at first, this system was soon in general practice. For the galleys Colbert encouraged magistrates to sentence common criminals to serving in them and had no scruple about other means of recruiting: political offenders, Protestants and slaves seized from Africa and Canada might all be made to serve.

Colbert reconstructed the works and arsenal of Toulon and founded the port and arsenal of Rochefort and naval schools at Rochefort, Dieppe and St. Malo. Calais, Dunkerque, Brest and Le Havre were fortified. The need for naval construction goes far to explain Colbert's vigilance over the forests (*Ordonnance des eaux et forêts*, 1669), one of the most corruptly administered sectors of the royal domain. As he also wanted the French ships of the line to have a handsome appearance, in order to impress foreigners, he engaged excellent artists, such as Pierre Puget, to decorate them. Encouragement was given to the building of ships for the merchant navy by allowing a premium on those built at home and imposing a duty on those built abroad; and as French workmen were forbidden to emigrate, so French seamen were forbidden to serve foreigners on pain of death.

**The Arts.**—Colbert was also concerned with the intellectual and artistic activity of the country in his capacity of secretary of state for the king's household (from 1669). It was necessary for the prestige of France to beautify towns and to protect scholars and writers, even foreign (pensions were given to Christian Huygens, Isaac Vossius and Nikolaes Heinsius). Also, the richness of the king's collections and of Colbert's own collection served to enhance their reputation throughout Europe.

Colbert, himself a member of the Académie Française, founded the Académie des Inscriptions et Belles-Lettres (1663) to choose inscriptions for medals and monuments celebrating the king's victories; the Académie des Sciences (1666) to study how the sciences could be exploited to the kingdom's advantage; and the Académie Royale d'Architecture (1671) to lay down rules and refine the taste of French work. He also founded schools, such as the Académie de France in Rome, in which artists could be trained under some of the great masters of the time; schools for practical purposes, such as the École des Jeunes de Langues, for the study of oriental languages; and the Observatoire in Paris, of which Giovanni Cassini was put in charge. G. L. Bernini was invited to submit a design for the Louvre, but its execution proved too expensive, so that plans by French architects were eventually adopted.

**Other Spheres of Activity.**—Colbert encouraged emigration to Canada to form the colony of New France, which had about

10,000 inhabitants in 1680. He promoted legislation on various matters; e.g., the *Ordonnance criminelle* of 1670, commercial laws and the so-called *Code noir* on slave labour. For agriculture he tried to protect the peasants so far as was consistent with his general economic system, to improve the breed of horses and sheep and to promote new crops. His concern for economic progress made him hostile to measures against the Protestants (many of whom were in business) and mistrustful of monks and of even the secular clergy (on the ground that too many men who should have been in commerce took holy orders). He himself remained a faithful Catholic.

**Conclusion.**—Colbert died in Paris on Sept. 6, 1683, a very rich man. His eldest son, Jean Baptiste, marquis de Seignelay, had been granted the right to succeed his father as secretary of state for the navy; the second son, Jacques Nicolas, was archbishop of Rouen; the fourth son, Armand, marquis d'Ormoys, was *surintendant des bâtiments*; and three of his daughters were married to dukes.

At the end of his life Colbert was a disappointed man. To profit from his reforms, the country needed peace, but the department of war was in the hands of his great rival, the marquis de Louvois (q.v.), who drew Louis XIV into a series of wars that counteracted all Colbert's planning. Even so, by energetically applying the authoritarian methods of the times, without distinction of persons or heed to public opinion, Colbert had made the monarchy stronger and the nation better equipped. Moreover, the order that he had introduced into the administration was to have a lasting effect. Though he did nothing to change the structure of society, Colbert treated all men as equals in so far as obedience to the king's orders was required of them.

Colbert left among his papers *Mémoires sur les affaires de finance de France*, written c. 1663; a fragment entitled *Particularités secrètes de la vie du Roy*; and other accounts of the earlier part of Louis XIV's reign. There is an edition of the *Lettres, instructions et mémoires de Colbert*, by P. Clément, 9 vol. (1861).

**COLCHAGUA**, a province in central Chile, lying between the Argentine border and the Pacific. Created in 1826, it has undergone various alterations in outline and administrative structure. It has an area of 3,215 sq.mi., and most of the 158,543 population (1960) lives in the longitudinal valley, where the production of wheat, rice, legumes, forage crops, grapes and tobacco is important. Numerous cattle and sheep are raised on valley pastures and range land in the coastal mountains and along the lower Andean slopes. Wheat and rice milling, tanning, and shoe and cigarette manufacturing reflect the dependence upon agriculture. This is the heart of the *huaso* or cowboy country and the rodeo at San Fernando (pop. [1960] 37,888 [mun.]) is among Chile's best. This city was founded in 1742 and became the provincial capital in 1840. It lies on the main line of the state railway and is the terminal for a branch railway that extends westward to the popular beach resort of Pichilemu. The paved longitudinal highway also serves San Fernando and the central part of the province. Lesser roads thread across the valley into the coast ranges and to some cordilleran spas and resorts. Important coastal salt evaporation ponds are operated south of Pichilemu; sulfur and copper deposits are reported for the Tinguiririca volcano area.

(J. T.)

**COLCHESTER**, a municipal borough in the Colchester parliamentary division of Essex, Eng., 22 mi. N.E. of Chelmsford and 50 mi. N. of London by road, on the river Colne. Pop. (1961) 65,080. Area 18.8 sq.mi. In pre-Roman and Roman history it was known as Camulodunum, the capital of the Belgic chief Cunobelinus (q.v.), and is named on his coins. After his death and

the Roman conquest, the emperor Claudius established a *colonia* of discharged soldiers. It was stormed and burned in A.D. 60 during the rising of Boadicea (q.v.) but soon became one of the chief towns in Roman Britain. Roman sculptures and inscriptions have been discovered and considerable stretches of the walls remain, forming a rectangle about two miles in extent and including the ruined Balkeine gate. Several excavated remains of buildings can be seen. In the vicinity are many dikes and earthworks. Domesday Book mentions Colneceaster with 276 burgesses and land in *commune burgensium*, a phrase that could point to a nascent corporation. The castle keep, built about 1070, is quadrangular, turreted at the angles, and is the largest of its kind in England. The quadrangle was roofed in 1930, and the castle houses a museum, chiefly of Romano-British antiquities of which it has the biggest collection taken from a single site in Great Britain. Medieval legend associates Colchester with Old King Cole of nursery lore. The Augustinian priory of St. Botolph (late 11th century) retains part of the fine Norman west front (in which Roman bricks occur), and of the nave and arcades; and there is the restored gateway of the Benedictine monastery of St. John, a beautiful specimen of Perpendicular work, embattled, flanked by spired turrets and covered with panel work. The church of Holy Trinity possesses the oldest church tower in Colchester, dating from 1050, an interesting specimen of late Saxon architecture. The Colchester Royal Grammar school was founded by Henry VIII in 1539.

The first charter was given in 1189 and new grants obtained in 1447 and 1535. Charles I granted another charter which was amended in 1653 and a new one granted in 1663; this one remained in force with modifications until 1741. In 1763 George III made a renewed grant of the town's liberties. Colchester returned two members to parliament from 1295 until 1885. Fairs were granted by Richard I in 1189 and by Edward II in 1319. In the 13th century Colchester was an important port, its ships plying to Winchester and France. Elizabeth I and James I encouraged Flemish settlers in manufacture of baize, and the making of clothing still flourishes. Both William Camden and Thomas Fuller mention the trade in barrelled oysters and eryngo (candied sea-holly root). Colchester was held, apparently against the citizens' will, by royalists in 1648 and it was fined in consequence.

The town is the centre of an agricultural district and has corn and cattle markets, besides extensive nurseries for roses and other plants. The chief industries produce agricultural implements, boilers and gas engines. The oyster fisheries at the mouth of the Colne belong to the borough corporation and are held on lease by the Colne Fishery company. The harbour, with quays at the suburb of Hythe, is controlled by the borough. The town is a military centre.

Colchester was made a suffragan see by Henry VIII, and two successive bishops were appointed by him after which no further appointments were made until it was re-established as a suffragan see of Chelmsford under Queen Victoria.

**COLCHICUM**, a genus of about 50 species of crocuslike herbs. The best known is the meadow saffron or autumn crocus (*Colchicum autumnale*), a perennial plant of the family Liliaceae

(q.v.), found wild in rich, moist meadowland throughout most of Europe. It has pale purple flowers, stemless, rarely more than three in number; the perianth is funnel-shaped, and prolonged below into a long slender tube, in the upper part of which the six stamens are inserted. The ovary is three-celled, and lies at the bottom of this tube. The leaves are three or four in number, flat, lanceolate, erect and sheathing.

Propagation is by the formation of new corms (bulblike structures formed by the enlargement of the stem base) from

T. H. EVERETT

MEADOW SAFFRON OR AUTUMN CROCUS (*COLCHICUM AUTUMNALE*)

the parent corm, and by seeds. The latter are numerous, round, reddish-brown and of the size of black mustard seeds. The corm of the meadow saffron attains its full size in June or early in July. A smaller corm is then formed from the old one, close to its root; and this in September and October produces the crocuslike flowers. In the succeeding spring it sends up its leaves, together with the ovary, which perfects its seeds during the summer.

The young corm grows continuously until the following July and attains the size of a small apricot. The parent corm remains attached to the new one and keeps its form and size until April in the third year of its existence, after which it decays. In some cases a single corm produces several new plants during its second spring by giving rise to immature corms. *C. autumnale* and its numerous varieties, as well as other species of the genus, are well known in cultivation, forming some of the most beautiful of autumn-flowering plants.

Colchicine, the alkaloid of *C. autumnale*, applied to the skin, causes pain and congestion; inhaled, causes violent sneezing; and taken internally, increases the amount of bile poured into the intestine. In larger doses it produces enteritis and nephritis with vomiting, diarrhea, hemorrhage from the bowel and ultimately death from collapse. This is accelerated by a depressant action upon the heart and nervous system. The sole medical use of colchicine is in gout. It lessens the severity and frequency of the attacks when given continuously between them, and benefits such symptoms of gout as eczema, bronchitis and neuritis, though inoperative against them when not of gouty origin.

Colchicine is a specific for doubling of chromosomes and is much used in genetics to produce new forms (see PLANT BREEDING: *Polyploidy*). (N. Tr.)

**COLCHIS**, the name given by ancient writers to the valley of the Phasis (modern Rion) river in Asia Minor, the region formerly known as Mingrelia in the west of the modern Georgian Soviet Socialist Republic. Colchis formed an almost triangular district at the eastern end of the Black sea, bounded on the north by the Caucasus mountains, which separated it from Scythia and Sarmatia, on the east by Iberia (equivalent to the modern regions of Kartalinia and Kakhetia) and on the south by Armenia, the Montes Moschici (modern Surami range), and Pontus.

The Colchians are first recorded early in the 1st millennium B.C.: inscriptions of the king Sardur (Serduri II, 750–733 B.C.) of Urartu mention his expeditions against Colchis. The Greeks regarded Colchis as the special domain of sorcery, a land of fabled wealth, as symbolized by the myth of the Argonauts (*q.v.*). Several colonies were founded there by settlers from Miletus, chief among them being Dioscurias (Roman Sebastopolis, modern Sukhumi). The Colchians supplied the Greeks with flax and linen cloth, agricultural produce, furs and skins, pitch, wax, timber, gold and slaves. The Greeks brought in salt, olive oil, pottery and fine textiles. Some ancient writers describe the Colchians as dark and woolly-haired, and akin to the Egyptians in language and customs; elsewhere they are depicted as yellow, fat and lazy from living in sultry and marshy valleys and drinking the stagnant waters of the Phasis—an allusion to malaria, prevalent in the region. Women were buried after death, the corpses of men exposed in trees. Excavations show that the land was covered with villages surrounded by orchards, vineyards and arable lands and connected by a network of roads and tracks and many bridges. Weaving, metalwork, carpentry and tanning were practised. The artistic and cultural influences of Hellenism spread among the upper classes. Colchis was long ruled by its own petty dynasts and tribal chieftains, who sometimes acknowledged nominal Persian suzerainty.

Early in the 1st century B.C., Colchis came under the rule of Mithradates VI Eupator, king of Pontus. Following the defeat of Mithradates by Pompey in 66 B.C., a Roman client ruler, Aristarchus, was installed. In 48 B.C., Pharnaces, son of Mithradates Eupator, revolted against the Romans in Colchis, but was soon expelled from the area by the armies of Julius Caesar. Colchis was then incorporated with Pontus (*q.v.*) under Roman rule. Various local kings were appointed or confirmed by the emperor Trajan and his successors. Arrian, the legate of the emperor

Hadrian, made an inspection of all the forts around the eastern Black sea coast including Phasis, described in his *Voyage Around the Black Sea*.

In the 4th century A.D., the weakening of Roman power in the eastern empire led the peoples of western Georgia to assert their independence. The Colchians became part of a new and powerful state, Lazica, which was for a time an ally of Rome; later, war broke out, leading to the expulsion of the Byzantines in A.D. 456. During the 6th century, Lazica was disputed between the Byzantine empire and the Persian empire under the Sassanid dynasty. The emperor Justinian I built a fortress at Petra, at or near the modern Batumi. The arrogance of the Byzantines alienated their Laz and Colchian allies, who revolted once more against Byzantine domination. In the peace settlement of 562 between Justinian and Khosrau (Chosroes) I, however, Justinian retained Lazica with Colchis.

In the 790s, Leo, duke of Abkhazia (northwestern Georgia), conquered Lazica and set himself up in Kutaisi as king of a new state, Abasgia, which included Colchis. Abasgia was in turn united with the other Georgian principalities by the king Bagrat III (975–1014), after which its history becomes merged in that of Georgia. In the 15th century, however, the breakup of the Georgian monarchy under the sons of Alexander I led to the emergence of the Dadiani as ruling princes in Mingrelia. Mingrelian autonomy was suppressed by the Russians in 1857. See GEORGIAN SOVIET SOCIALIST REPUBLIC: *History*.

**COLD:** see LOW-TEMPERATURE PHYSICS; METEOROLOGY; REFRIGERATION; THERMOMETRY.

**COLD, COMMON.** The term cold (head cold, chest cold, etc.) is applied in the most general way to various maladies of the respiratory tract (see RESPIRATORY SYSTEM, DISEASES OF). Most specifically it means coryza (formerly called nasal catarrh), of which the typical symptoms are inflammation of the mucous membranes of the nose (rhinitis) accompanied by a profuse nasal discharge. At onset there is often dryness or irritation of the throat and sometimes a sensation of chilliness. In the early stages the nasal discharge is watery but in two or three days it becomes thicker and contains some pus. Involvement of the paranasal sinuses and the lower respiratory tract, with coughing, is common.

Colds and their complications are responsible for much discomfort and disability. A survey showed that in one week in November, colds were reported in one-third of U.S. homes; *i.e.*, approximately one person in seven was afflicted with a cold. Other surveys indicate that approximately 75% of the people have at least one cold each year and 25% have four or more. Studies indicate that the common cold and its complications are a major cause of loss of time in industry. The annual cost in the U.S. (economic loss and expenditures for drugs and medical and hospital services caused by the common cold and its complications) has been estimated as between \$2,000,000,000 and \$3,000,000,000.

**Cause.**—As the name suggests, colds are widely but inaccurately believed to result from chilling—a condition that does, in some persons, cause sneezing. Attacks of hay fever (*q.v.*), in which sneezing and nasal congestion are caused by an allergy to some substance in the air (*e.g.*, pollen), often are mistaken for colds, particularly in the spring of the year.

The common cold is communicable, and occurs in waves throughout the year, usually in early autumn, midwinter, and early spring. A majority of such colds are seemingly caused by a virus (*q.v.*). Colds are particularly difficult to study because none of the techniques ordinarily used in investigating virus diseases is effective. The only test for the presence of a cold virus is production of a cold by dropping material up the nose of a human subject or a chimpanzee; other animals are not susceptible. Walther Kruse first showed in 1914 that colds could be transmitted with filtrates.

In the early 1920s A. R. Dochez and his collaborators extended these findings and first showed that chimpanzees could be infected. Claims to have cultivated the virus in eggs were not substantiated, however.

Since 1946 colds have been under continuous study by a team of workers under the Medical Research Council at the Common Cold Research Unit at Salisbury in southern England. Their main object has been to find a way of studying the virus readily in the laboratory. Normal volunteers are isolated from other people in pairs for ten days. After a short period of observation they undergo intranasal instillation of cold virus or other material under test. They are then observed for another week to see whether a cold develops. Under these conditions, filtrates of nasal washings from colds will transmit infection, though rarely to more than 50% of those inoculated. Such colds can be similarly passed on in series to other subjects; a multiplying agent is therefore clearly concerned.

The incubation period is usually around 48 hr. though for at least one strain of virus it is a day or two longer. Nasal discharge is a constant feature; fever is rare. The virus is smaller than the quite distinct influenza virus: probably about 0.05 micron (0.00005 in.) in diameter. It can be preserved for years at  $-76^{\circ}\text{C}$  in dry ice. It is destroyed outside the body by ordinary antiseptics, but like other viruses is not affected by antibiotics such as penicillin. Attempts have been made to grow the virus in cultures of living tissues, especially human embryonic tissues, without definite success.

Workers at Bethesda, Md., and in Washington, D.C., were successful, after 1953, in growing in tissue culture viruses causing fever and sore throats, and sometimes conjunctivitis; these came to be called adenoviruses. Vaccines against them showed promise. Adenovirus infections, however, though they may resemble common colds, are distinct from them and are unimportant in civil life, though often troublesome among recruits in the armed services. Further reports of cultivation of viruses from minor coldlike illnesses were probably not typical colds. It is uncertain whether there is one common cold virus or many.

**Spread of Colds.**—Colds can obviously be spread if a cold victim sneezes in another person's face. Apart from that, cross-infection seems to occur especially from prolonged and intimate contact. Children seem to transfer infection to others more easily than do adults. In a rural community, adults in households containing schoolchildren had  $2\frac{1}{2}$  times as many colds as had adults not closely associated with schoolchildren. Small particles of virus remaining suspended in the air can convey infection; but breathing such remotely infected air does not lead to catching cold as easily as does closer contact, and handling contaminated articles seems even less infective.

Bacteria of various types have also been described as a cause of colds; their role, however, seems to be mainly that of secondary invaders following virus colds. Climate is much less a factor in the occurrence of colds than is generally supposed. Studies by the U.S. Public Health Service show that the attack rates of colds in college students and family groups in various parts of the country are remarkably uniform and show no consistent relationship to latitude, longitude, or climate. These studies also show surprising similarity in the time of occurrence in various sections of the country. Studies in isolated Arctic communities indicate that epidemics of colds are related not to temperature but to contact with infected persons. Persons isolated for many months find when they return to civilization that they are then more prone to infection than normally. This suggests that resistance is maintained by repeated contact with tiny doses of infection; in the absence of such contact, resistance tends to wane.

In the tropics colds are less common and less severe, but they do occur and present a miniature picture of colds in temperate regions. Despite the widespread association between cold and colds, evidence to support this notion is lacking. Experiments have been carried out in which human subjects have been chilled by standing about in drafts in wet bathing suits, by wearing wet socks, by going for walks in the rain; yet no colds were induced, nor were the subjects abnormally susceptible to administration

of small doses of common cold viruses. Possibly the association has arisen from the sensation of chilliness that is sometimes the earliest symptom of a cold. Undoubtedly colds are commoner in winter than in summer, possibly because people tend to collect closely together indoors during the winter.

**Complications.**—An uncomplicated cold runs a short, relatively mild course of a few days' duration. The complications, however, are numerous and important. Of these, the commonest are sinusitis, otitis media (infection of the middle ear), and infections of the lower respiratory tract, such as laryngitis, tracheitis, bronchitis, and pneumonia. Closely allied but distinct diseases are influenza and some types of sore throat. The paranasal sinuses are lined by mucous membrane that is continuous with the membrane of the nose; some inflammation of the sinuses, therefore, probably follows most if not all acute head colds (see SINUS). Otitis media occurs from the nose and throat by way of the Eustachian tube. Otitis media was often complicated by mastoid infection, but this is largely controllable by antibiotics.

**Prevention.**—Natural resistance plays an important role in a person's susceptibility to colds. Studies from Cornell University (Ithaca, N.Y.) indicated that 25% of the students had approximately 75% of the colds there. In many persons, however, susceptibility seems to vary over the years. Defensive mechanisms against infection are the hairs at the entrance of the nasal passage, the mucous secretions of the membranes lining the nose, and the cilia (tiny hairlike projections in the membranes). It is important that these natural defenses not be destroyed or interfered with.

Under the conditions of modern life it is impossible to avoid exposure to persons with colds. People with colds, however, can refrain from infecting others by avoiding crowded places. Unfortunately an infected person is infectious even before symptoms begin, so that no amount of care can altogether stop the spread of colds.

Vitamins and various measures are widely advocated and advertised for the prevention of colds, but no conclusive scientific studies indicate that a special diet or vitamins has this effect. Vaccines have long been used for the prevention of colds. In general, they consist of killed bacteria of the types usually found in the nose and throat during colds. Some of these vaccines are given by mouth, some by hypodermic injection, and a few by spraying into the nose. Carefully controlled studies in which half the subjects received vaccine while the other half, chosen at random and without their own knowledge, were given material containing no vaccine show that the subjects who received the vaccines had as many colds as the subjects in the control groups, and subjects in both groups reported considerably fewer colds than they thought they had had during the previous year. Various antiseptic sprays, nose drops, gargles, and mouth washes have been recommended. Antiseptics do not act to kill germs instantaneously; only mild antiseptics can be tolerated by the membranes of the nose and throat, and these can be brought in contact with only a small portion of these membranes and for only a few seconds at a time. There is therefore no reason to think, and no scientific evidence, that antiseptics are of any value for the prevention of colds or other respiratory infections. On the contrary, there is danger that at least some of these preparations interfere with the normal protective action of the cilia and mucous secretions in the nose. Sterilization of the air by ultraviolet light or chemical vapours is theoretically sound but impractical.

**Treatment.**—A cold usually runs its course in three to ten days. If nasal discharge persists longer, a complicating infection of one of the sinuses should be suspected. As recovery progresses, the nasal congestion decreases and the secretions become scanty and more purulent. Most treatment is directed toward the relief of symptoms. Bed rest is advisable in the early stages of a severe cold to protect others from exposure, increase general resistance, and keep the body warm. Hot baths dilate the blood vessels of the skin and increase the blood flow through them and thus reduce nasal congestion and stuffiness. Such relief is only temporary. Large quantities of liquids are frequently recommended, but their value is open to question. Advertised and recommended treat-

ments are legion; most of these do little more than give some temporary relief of certain symptoms. The salicylates, such as aspirin, and similar drugs give some relief from aching and reduce fever. Nose drops and inhalers of various types shrink the membranes of the nose and so give temporary relief of stuffiness and nasal congestion. Unfortunately, use of these drugs frequently results in more swelling than was present before. Most preparations stop the action of and often actually destroy the cilia.

Experiments over a period of approximately five years were conducted in which subjects were all treated in the same manner and all thought they were receiving the same medication. The control group received placebos. Approximately 35% of the control subjects reported that "the medication resulted in complete cure or marked improvement of their colds in 24 to 48 hours." Such results explain why it is so easy to become enthusiastic about any preparation for the treatment of colds. Most of these preparations are of no more value than sugar tablets. Studies have shown that there is no justification for the use of antihistamine drugs, sulfonamides, or antibiotics; on the contrary, some persons have undesirable reactions to these drugs. Also, if these drugs are used for colds, strains of germs that are resistant to them may develop; and the drugs become valueless for the treatment of severe infections. (C. H. As.)

**COLDEN, CADWALLADER** (1688–1776), American physician, philosopher, scientist, historian, politician, and colonial official, was born on Feb. 7, 1688, in Ireland where his mother, the wife of a minister of Duns, Scot., was visiting. He was destined by his family to enter the ministry but his studies at the University of Edinburgh aroused his interest in science. After receiving his A.B. degree in 1705, he went to London to study medicine. In 1710 he emigrated to Philadelphia, Pa., where he engaged in a general mercantile business and in the practice of medicine. A promise by Gov. Robert Hunter that he would be appointed master in chancery and surveyor general of New York led to his moving to that colony in 1718. These appointments were duly made in 1720 and one year later he became a member of the governor's council. This was the beginning of a public career that was continuous until his death and was culminated with the lieutenant governorship (1761–76). His biographer sums up his public career as follows: "Whether straightening out with industrious skill the tangle of the colonial lands; demonstrating the ease with which huge patents could be automatically reduced by the exaction of legal quit-rents, which, in turn, could be used as a salary fund to insure the independence of crown officials; formulating an Indian policy; or, discredited, living in watchful retirement . . . , he never ceased to fight colonial aggression with the same indomitable resolution which characterized everything he did." In the historical setting in which this efficiency and dedication were exercised, only failure and frustration could result.

Colden had that remarkable versatility of mind so characteristic of the intelligentsia of his age. As a physician he contributed to medical knowledge with studies of cancer, yellow fever, smallpox, and the effect of climate on disease. His scientific interests and observations encompassed physics, astronomy, chemistry, botany, and what would now be called psychology. He classified the flora around his New York estate according to the Linnaean system and had the pleasure of having his work praised and published by the Swedish botanist. His *History of the Five Indian Nations* published in 1727 is still useful. Philosophically, he was first and foremost of the early American materialists.

He died at his Long Island estate on Sept. 28, 1776.

**COLD HARBOR**, OLD and NEW, two localities in Hanover County, Va., U.S., 10 mi. NE of Richmond, which were the scenes of two battles of the American Civil War. The first (sometimes called the battle of Gaines's Mill) was fought June 27, 1862, between the army of the Potomac under Gen. G. B. McClellan and the army of northern Virginia under Gen. R. E. Lee. The second encounter was a succession of battles from May 31 to June 12,

1864, between the Union forces under command of Gen. U. S. Grant and the Confederates under Gen. R. E. Lee, who held a strongly entrenched line at New Cold Harbor. See AMERICAN CIVIL WAR.

**COLDSTREAM**, a small burgh of Berwickshire, Scot., 48 mi. SE of Edinburgh, on the north bank of the Tweed River. Pop. (1961) 1,226. Coldstream played a prominent part in Scottish history. There Edward I forded the stream in 1296 with his invading army, and the 5th earl of Montrose crossed with the Covenanters in 1640. No trace remains of the Cistercian abbey founded about 1165 by Cospatrick, 3rd earl of Dunbar, and destroyed by the 1st earl of Hertford in 1545, which adjoined the present market place, but for nearly 400 years it was a religious centre. In the reign of Henry VIII the papal legate published a bull there against the printing of the Scriptures, but the site was occupied in the 19th century by an establishment, under Adam Thomson, for the production of cheap Bibles. At Coldstream Gen. George Monck crossed the Tweed in 1660 with the regiment raised there, now famous as the Coldstream Guards.

Like Gretna Green (*q.v.*), Coldstream was long a resort of runaway couples, the old tollhouse at the bridge being the usual scene of the marriage ceremony. Although unused, Marriage House, as it is called, still exists. Among the chief industries of Coldstream are agricultural engineering, knitwear, and cold-process bakery.

**COLD WAR**, a term loosely used to describe the power struggle, with its political, diplomatic, and ideological conflicts and military threats, that arose after 1945 between the Communist and the Western democratic-capitalist nations—especially between the Soviet Union and the United States. It had no specific beginning nor by the late 1960s had it reached any clearly defined conclusion. The history of the cold war is virtually the whole history of international politics since 1945, and it can be followed here only in very broad outline. While cold war, like peace, is indivisible, four major phases may, for convenience, be distinguished: (1) the close of World War II, 1945–49; (2) expansion of the cold war, 1949–53; (3) emergence of new international power structures, 1953–62; and (4) the latest phase, 1962–67.

#### THE CLOSE OF WORLD WAR II (1945–49)

While the term "cold war" was not generally current until 1947, the thing itself was clearly incipient in the closing years of World War II. The unconditional surrender demanded of Germany and Japan clearly must leave a power vacuum around the periphery of the Soviet Union, and there was no agreement, nor even a basis for agreement, among the prospective victors as to how it should be filled. An earnest effort was made at Yalta (February 1945) to compromise the conflicting political and territorial claims and to frame a world system under which both the Soviet Union and the Western powers could live in peace. It was a failure. (See WORLD WAR II CONFERENCES, ALLIED: *Yalta*.) The supposed agreements on the future of Germany and Eastern Europe, on the organization of the United Nations, and on the ending of the war in the Far East were differently interpreted by the two sides. These supposed agreements were to lead to much recrimination and many allegations of bad faith; but they supplied no workable solutions for the huge problems raised by the political and moral chaos to which the war had reduced international society.

**Drawing the Lines.**—While bad faith as well as misunderstanding may have played its part, the failure at Yalta was in any event inevitable. The Soviet and the Western statesmen were committed to mutually irreconcilable concepts of international order. In general terms, the West wished and believed it possible to reestablish an international system essentially (with some modifications) like that which Hitler had destroyed in 1939. This implied the restoration of the Eastern European states and other liberated areas—wracked as they were by the savagery, bloodshed, and embittered factionalism of the occupation years—under "free" governments of their own choosing. It implied that the vast areas surrounding the Soviet Union, from China to the Balkans, would remain substantially under Western tutelage. The Soviet Union would be accepted as a great Communist state in

its own right, but its dynamic potentialities would be restrained under a general system of law and order supervised by a Western-dominated United Nations.

The Soviet statesmen, on the other hand, had no intention of restoring the prewar power structure; nor was it, perhaps, any longer possible to do so in the harsh world of 1945. Brought up in a school in which the seizure of power, by fair means or foul, was the essence of practical politics, they were inclined to regard Western concepts of law and popular government as either naive or hypocritical. They had no faith in a United Nations that they could not dominate. They had no interest in or respect for "free" elections as determinants of basic power issues. It is questionable whether they ever actually entertained those dreams of world domination so often alleged against them on the evidence of their own utterances, but there is no doubt that they intended to reshape the prewar power system in terms more favourable both to Communism and to the U.S.S.R. They intended to regain the frontiers lost to Russia after World War I and to protect themselves against a repetition of the horrors and devastations of the Nazi onslaught. Beyond their frontiers they insisted on establishing "friendly" governments so firmly under Soviet control that they could not again serve as avenues for Western capitalistic attack. They wanted either to remove Germany's capabilities for aggression or to ensure their own control over the defeated country. And they intended to secure for the U.S.S.R. an authoritative voice in an international society from which it had been largely excluded since the Bolshevik Revolution.

Between these clashing political and power interests, clothed on the two sides in wholly incompatible ideologies, war of some kind was unavoidable. In the earlier years it was widely believed in the West that only the U.S. monopoly of atomic bombs prevented the Soviet Army from overrunning the whole of Western Europe. However that may be, the Soviets possessed weapons not only immune to atomic bombs but considerably more effective as practical instruments of power in the context of the times. The Leninist vision of world proletarian revolution was hardly any longer a goal of Soviet policy, but it remained its most powerful weapon. In France and Italy there were large indigenous Communist parties, their prestige enhanced by the great Soviet victories and by their own contributions to the Resistance, and they presented a real threat of a Russian conquest of Western Europe by at least quasi-constitutional means. In Central Europe, on the other hand, the Communist parties were small; but as the Soviet armies rolled on toward their victory in Berlin the local Communists were installed in the anterooms of power.

Poland, representing the first major Soviet victory in the cold war, came to be seen as typical of all the rest. The history is as complicated as it was tragic. The Russians established their own creation, the "Lublin Committee," in power in the wake of their armies. The West, forced reluctantly to recognize it in July 1945, could not avert the complete Communist takeover which soon followed. The Russians had their armies on the ground and the West did not. With greater or less rapidity the process of bringing the Central European states first under Communist domination and then under full Communist control continued, with the West incapable of halting it.

The fears and tensions engendered in the West by these takeovers became more acute. When Stalin, in February 1946, implied in a formal speech that a peaceful international order was impossible "under the present capitalist development of the world economy" and called for a massive program of industrial reconstruction and expansion, many in the West took it as a declaration of World War III. In the following month, Winston Churchill made his celebrated pronouncement that from the Baltic to the Adriatic an "iron curtain" was descending across Europe; behind it the "very small" Communist parties were being raised to a power far beyond their numbers; everywhere police governments prevailed and "there is no true democracy." He summoned the non-Communist world to resist in the name of freedom. The Russians denounced him as an anti-Soviet warmonger. If this was not, as it is often considered, a first declaration of cold war, it at least set the mold in which Western thought and Soviet thought

alike were thenceforth to address the global problem.

Thus by early 1946 the lines were drawn; they were not yet rigid. There were many in the West who were critical of the Churchill speech, who questioned Pres. Harry S. Truman's increasingly "tough" policy toward the U.S.S.R., and who still hoped for a working understanding with the Soviet Union. In the Pacific the same underlying issues were appearing, but there the military balances were more even and a kind of rough equilibrium was established for the time being. The United States successfully excluded the Soviet Union from any share in the occupation of Japan but had to accept the *de facto* partition of Korea, with the North passing promptly under a Communist dictatorship while the South maintained at least the appearances of democracy. In northern China Mao Tse-tung's powerful native Communist movement had long been battling both against the Japanese and against the anti-Communist government of Chiang Kai-shek, whose authority the West was trying to reestablish. But Moscow's attitude remained somewhat ambiguous. In Indochina a Communist-led guerrilla movement was rising against the French—initially with some American encouragement. Communist revolutionary movements were forming elsewhere in Southeast Asia. But Far Eastern questions were remote to Western eyes and not yet seen in the harsh contexts of cold war. At the end of 1945 Gen. George C. Marshall, the wartime U.S. chief of staff, was sent to China in the hope of securing peace and reconciliation between the Communist and the Nationalist factions—a hope which suggests how imperfectly the patterns of cold war were then understood in Washington.

**Germany and Eastern Europe.**—In Europe, however, cold war, centring in the struggle over the fate of Germany, was already inescapable. Subordinate to this were many other issues—the fate of the East European states; a Communist guerrilla war in Greece; Soviet reluctance to evacuate Iran; control in the UN; and the problem of disarmament, the last always insoluble but now rendered doubly so by the U.S. atomic monopoly. But it was in Germany that the cold war took rigid form, as a major battle for the resources, for the military potential, and ultimately for the allegiance of the defeated Germans. Under its stresses, the four-power control system set up after the armistice rapidly became unworkable. The first serious issue arose over Soviet demands for reparations deliveries from the Western occupation zones; and when the Western powers in April 1946 simply suspended further reparations deliveries, it indicated a divergence of interests too deep to make a genuinely joint control any longer possible. The joint agencies—the Allied Control Council for Germany and the Kommandatur for Berlin—were to survive for some time, but they were to survive mainly as arenas in which the cold war was waged. The Russians reestablished a Communist Party in East Germany which by the fall of 1946 was in effective control of their zone; the Americans and British merged the economies of their areas into "Bizonia," the foundation of what ultimately became the West German Republic. Each of the great power blocs was committed to the reunification of Germany, but only on its own terms; each had begun the process which was to make division inescapable.

As the Russian Communist absorption of Eastern Europe continued toward completion, as the Soviet pressure in Germany intensified, and as General Marshall returned to the U.S. at the year's end with his mission in China a total failure and Communist victory in the Chinese civil war a probability, Western fears and tensions mounted. The U.S. president felt that the time had come to call a halt. In March 1947, utilizing Britain's need for relief in Greece, he announced in the Truman Doctrine that "it must be the policy of the United States to support free peoples who are resisting attempted subjugation by armed minorities or by outside pressures." To the president himself this was a turning point in U.S. policy: It was clearly the beginning of the policy of "containment," soon to be expounded by George F. Kennan (in an anonymous article in *Foreign Affairs*, July 1947). Kennan argued that the expansionist and aggressive tendencies of the Soviet Union could and should be contained, by whatever means were available, until such a time as inevitable growth and change

within Russia might render those tendencies less perilous to the free institutions of the West.

By this time the phrase "cold war" was generally current in the West, expressing the sense of a bitter conflict, though one still waged without the clash of armies. The Truman Doctrine did not pass without challenge, both as rendering any rational adjustment with Russia impossible and as committing the United States to tasks beyond its powers; but the pattern it set found overwhelming support in American opinion. The aid proffered to Greece and Turkey in March 1947 was followed in June by the proposal of the Marshall Plan for the economic rehabilitation of Western Europe. The Marshall Plan was to prove amazingly successful. It was also to force the issue in Europe and precipitate the greatest single crisis of the cold war.

The Soviet statesmen saw that the rebuilding of Western Europe by American capital not only would blunt their principal power weapon—the further export of Communist revolution—but also would threaten their hold upon their shaky satellite empire in Central Europe. The satellites were forbidden to participate in Marshall Plan aid. Czechoslovakia, the last Eastern European country to maintain the democratic forms in uneasy coalition with its Communists, moved to accept the aid but was forced to withdraw; and in February 1948 the Beneš government succumbed suddenly to a Communist coup. To the West the shock was severe. Except for Berlin, the Soviet subjugation of all Europe up to the Elbe River was complete; and Western fears of a military onslaught that would swallow the rest were intensified. France, Britain, and the Benelux powers (Belgium, the Netherlands, and Luxembourg) established a defensive alliance with the Brussels Pact (1948), while the West pressed forward with its plans for reforming the shattered West German currency and ultimately establishing West Germany as an independent state. The Soviets, still intent on securing the whole of Germany for Communism and unable to withstand the impact of a reformed West German currency on their East German economy, set themselves to defeat both ends.

They could do little to block the plans of the Western Allies for the rehabilitation of West Germany. But Berlin, still nominally undivided under the four-power control, was deep within Communist East Germany, at once a threat to the Soviet system and a hostage in its hands. The Russians used every device to put the Berlin Communists in command of the city's administration, while they began tentatively to interrupt the city's economic ties with the West and the access of the Western powers to their sectors in West Berlin. When the West announced in June that it would extend the new West German currency to Berlin, the Russians responded by cutting off all road and rail traffic into the Western sectors of the city; the blockade of some 2,000,000 Germans in West Berlin had begun. The object was to establish the position that Berlin as a whole was a part of East Germany and its economy; to force the Western powers out of the city; and thus to seize the traditional German capital for Communism.

The West's military force was at a low ebb; the point about the currency was not without force, and the West's own attitudes toward the defeated Germans were still ambiguous. The West might have abandoned the struggle; but the uncompromising attitude of the non-Communist Berliners themselves, together with the unexpected success of the airlift that sustained the Western sectors through the autumn and winter, averted what would have been a disastrous defeat for Western power and prestige. The complex political and propaganda battles that ensued, as well as the effectiveness of the airlift, made it apparent that neither side could win the city, except by an open war which neither side wanted. In May 1949 an agreement among the four occupying powers (the U.S., U.K., France, and U.S.S.R.) raised the Berlin blockade and counterblockade, settled the currency question, and in effect divided Berlin, as Germany had already been divided, into Eastern and Western sectors.

**Stabilization.**—Clearly, the world was in no less peril than before, but a certain stabilization had been achieved. The guerrilla war in Greece had been suppressed, partly by virtue of U.S. aid, partly through the expulsion of Yugoslavia from the satellite sys-

tem, which deprived the Greek Communists of their base. In April 1949 the North Atlantic Treaty Organization (*q.v.*) was established, replacing the Brussels Pact with an Atlantic alliance which, if still without hard military content, was a more formidable barrier to further Communist expansion. The large Communist parties in France and Italy had been excluded from the governments of the two countries and no longer seemed seriously to threaten social revolution in the interest of Russian power. The war for Germany was undecided; but it had at least been transformed from the confusion of joint control into a clear-cut issue between East and West. The German Federal Republic was established as a self-governing state in West Germany and West Berlin (August 1949); and the Soviets were shortly to follow suit by setting up the German Democratic Republic in the areas under their control.

By the summer of 1949 the worst issues arising directly out of World War II had thus been resolved, compromised, or reduced to uneasy stalemate. Europe had been divided but at the same time restored. Japan was being rebuilt as a formidable, if non-military, bastion of Western power in the Pacific. The Soviet Army, maintained at high troop levels and being rearmed with modern weapons, posed a threat; but the United States, with the atomic monopoly, was, like the other Western powers, more interested in cutting military expenditures than in maintaining strong defense forces. The policy of containment seemed to be succeeding, and the elements at least of a *détente* in the cold war were appearing, when two unsettling events supervened.

On Sept. 23, 1949, President Truman announced that an atomic explosion had occurred in the Soviet Union. The atomic monopoly was at an end, and the chief foundation on which Western military policy had rested since 1945 had slipped beneath the statesmen's feet. And at about the same time the Communist conquest of China had been completed. The remnants of the Nationalists had been driven to Formosa, and the Chinese People's Republic was proclaimed at Peking on Oct. 1. In the United States there were bitter recriminations over this "loss" of mainland China. The ill-founded ideas that Soviet espionage had stolen "the secret" of the bomb, and that U.S. policies which seemed to have contributed to the Nationalist disaster had sprung from Communist or pro-Communist influences in the State Department, arose at once to set the cold war in still more rigid and embittered patterns. And at this point Communist North Korea, in June 1950, launched its well-trained army upon South Korea. The international situation was transformed.

#### EXPANSION OF THE COLD WAR (1949-53)

**Korean War: Beginning.**—Josef Stalin left no known account of his motives in instigating, or at least authorizing, the Korean War (*q.v.*). Speculation has suggested various possibilities. Checked in Central Europe, he may merely have seen an opportunity to pick up an easy countervailing victory in the Far East. Western "imperialism" may not even have been the primary target. In January 1950 Dean Acheson, the U.S. secretary of state (reflecting the views of the Joint Chiefs of Staff), had drawn an American "defense perimeter" in the western Pacific which excluded both Korea and Formosa. It is not impossible that the North Koreans may have forced Moscow's hand by initiating the war on their own account, and that Russia's refusal to disavow them was dictated more by the necessity for maintaining the Soviet power position (and forestalling the rising power of the Chinese under Mao Tse-tung) than by any desire to attack the West. The motivations may well have had more to do with the complicated politics of Asia than with the cold war itself. To the West it did not seem so. The assault on South Korea was at once assumed to presage a general onslaught upon the free world. "Communism," as the U.S. chief of staff, Omar Bradley, declared in 1950, "is willing to use arms to gain its ends. This is a fundamental change."

U.S. military appropriations were abruptly quadrupled, but most of the money went to the defense of Europe rather than to Korea. NATO was converted into a full military alliance with a common command and staff system under the wartime supreme

commander, Dwight D. Eisenhower. Plans were rapidly formulated for raising American occupation forces in Germany from two to six divisions and, ultimately, for rearming West Germany and incorporating its forces in the common defense. An intense effort was already under way in the United States to develop a thermonuclear bomb, a thousand times more powerful than the sufficiently terrible weapons deployed against Japan. Meanwhile, President Truman, throwing what troops were available into Korea, obtained from the UN Security Council a vote authorizing a multinational "police action" under U.S. command for the rescue of South Korea. It escaped a Soviet veto only because the Russians were at the time boycotting the council in protest against the exclusion of Communist China from the UN.

After an initially desperate defense, the military position was restored by the beginning of October 1950; the resort to "hot" war had cleared South Korea up to the original boundary along the 38th parallel. The decision of the United States government, endorsed by the UN General Assembly (the Russians, having returned to the Security Council, interposed the veto against any further action by that body), to press on and recover North Korea from the now defeated Communists was dictated less by military than by cold war considerations: to punish and put an end to Communist "aggression" everywhere; to reunify a "free" Korea and so vindicate the Truman Doctrine; to establish the controlling authority of the United Nations as a power for peace and justice. But the results were lamentable. Unknown to the American-UN command, China had passed some hundreds of thousands of its own troops into North Korea. In the middle of November these struck in a devastating surprise attack which could not be stemmed until all of North Korea and a large fraction of the South had been lost. President Truman's reaction is suggestive: "Because this new act of aggression in Korea," he declared, "is only part of a worldwide pattern of danger to all the free nations of the world, it is more necessary than ever before to increase at a very rapid rate the combined military strength of the free nations." But a great increase in Western military strength was not the only answer, and possibly not even the most significant one, to the threat of Communist expansion. While the hot war dragged on for another two years in Korea, absorbing much of Western attention, the cold war was continuing in other areas of the globe where it was beyond control by atomic threats or massive troop formations.

**Further Communist Penetration.**—Communist movements had for years been in existence throughout Southeast Asia, seeking to exploit by typically undemocratic methods the powerful forces of nationalism and anti-imperialism sweeping the Eastern world. World War II had opened to these movements even more complex opportunities than those it had brought to Communism in Europe. In the Japanese victories of the early war years Western imperialism had been defeated and destroyed by an Asian power; Asian nationalist and resistance forces had in turn played their part in the defeat of the Japanese. It was the power of the United States rather than of the old European imperialisms which conquered Japan in the end; and American policy, until hardened into the rigid frame of anti-Communist cold war, was ill-defined and often self-contradictory. By the autumn of 1945 Ho Chi Minh, a long-time and unusually able leader of Asian Communism, had proclaimed his Democratic Republic of Vietnam in Hanoi. By the end of 1946 the effort of the French to reestablish their control and influence in Indochina had deteriorated into a guerrilla war in Vietnam which the French were not winning. By 1948 there were Communist-inspired armed uprisings in the Philippines, Indonesia, Malaya, Burma, and parts of India. Lesser Communist penetrations took place in the Middle East and North Africa. Here Soviet policy (after the Russian withdrawal from Iran) had remained quiescent, and the cold war was largely one of virulent propaganda; but the threat of Communist subversion and disruption remained. And the thunderclouds of the atomic arms race and of the German problem continued to overhang international society.

**Doctrinaire Anti-Communism.**—It is not surprising that the cold war took on a deeper passion and intensity. To most in the

West by this time "atheistic Communism" had assumed the aspect of a vast and monolithic conspiracy of evil against all the values, political and moral, that the West believed itself to stand for. The promises of Communism were seen as valueless; its methods were violent, mendacious, and conspiratorial; its declared goal was the domination of the world; and its victories were irreversible. Free peoples retained in theory their power to determine their own forms of government, but once the Communists had seized power and established the police state there was no possibility of overthrowing it. The conquered people passed into a "slavery" from which there was no escape.

Clearly, this view of the world problem had many defects; it was in many ways no more than a mirror image of the view of Western "imperialism" and "aggression" held up by the Communist propagandists, and at many points it accorded hardly better than the Communist view with the inordinately complicated facts of world politics which it sought to control. Yet the cold war cannot be understood without taking into account this concept of the "Communist menace," dominant in most Western thought and overwhelmingly so in that of the United States. However oversimplistic, it was emotionally compelling, and it imposed on American and Western policy a doctrinaire rigidity which was to render impossible compromises and adjustments that might otherwise have been achieved. And perhaps because it was not notably successful in containing Communism abroad, it tended, especially in the United States, to turn the cold war inward into an impassioned assault on domestic Communism. The Korean War period saw a fierce attack upon Communist espionage, infiltration, and subversion in the United States, and upon the Communist ideology itself, from which these perils appeared to spring.

"McCarthyism," as it came to be called, had roots long antedating the rise of Sen. Joseph R. McCarthy (*q.v.*). As early as the summer of 1946 a Canadian Royal Commission had revealed the existence of Soviet espionage networks in Canada and the United States, found to be largely recruited from native Communists and their sympathizers. Later, a few Communist "cells" were discovered in the middle ranks of the Washington bureaucracy. In 1947 President Truman instituted a fairly sweeping internal security system to bar Communists and Communist sympathizers from federal employment. The sensational case of Alger Hiss, a higher official, accused on what amounted to charges of Soviet espionage, absorbed the public attention and added to the anti-Communist excitement through most of 1949. It was after Hiss was convicted in January 1950 that Senator McCarthy put himself at the forefront of a virulent campaign to root Communists and those suspected of the Communist taint not only out of government but out of defense industry, the universities, the arts, the press, and many other facets of American life.

What the internal menace actually amounted to is difficult to say. While there were Communist cells in government it was never convincingly shown that they distorted policy because of a pro-Russian allegiance. The espionage networks were real; but such of their exploits as came to public knowledge seem fairly trivial. Even the atomic espionage, for which Alan Nunn May and Klaus Fuchs were imprisoned in England and Julius and Ethel Rosenberg were executed in the United States, cannot have materially hastened the Soviet development of nuclear energy. There can be little doubt that the domestic dangers of Communism were hysterically exaggerated; at any rate Senator McCarthy finally overreached himself and a saner perspective was restored. Yet in the result Communism was effectively extirpated in the United States either as a political force or as an organized conspiracy, while the cold war psychology froze more deeply than ever over American foreign policy.

**Korean War: End.**—In December 1950, at the height of the debacle in Korea, American-UN policy had openly renounced the reunification of the country as a military objective. While there could be "no thought of appeasement or of rewarding aggression" anywhere, the West was prepared to negotiate a truce on the original frontier, leaving unification to be attained later by "peaceful" means. By March 1951 the U.S.-UN armies, after hard fighting, were back substantially on the 38th parallel. Two heavy

Communist offensives thereafter were successfully repelled; the war had been fought demonstrably to a draw. As the result of a Soviet initiative, the UN command asked at the end of June for armistice discussions. The Chinese and North Koreans agreed to discussions, but it was not until two years later that they at last agreed to an armistice.

The last two years of the Korean War (which, with both sides on the strategic defensive, were still to cost the Americans alone three-quarters as many casualties as had the first year) were a baffling and exasperating experience for the American commanders and policy-makers. They were accustomed to thinking of cold war as the other side's substitute for a hot war it did not dare to risk. Here, however, the hot war had been risked and in effect decided, which by ordinary standards should have ended the matter. Yet the fighting dragged on, not for normal military objectives but for political, cold war objectives to which the bloodshed was merely ancillary. While the war continued in the rocky hills beyond, the Chinese used the interminable negotiations in the Panmunjom truce tents to secure political and propaganda victories, to tire out the West, to extort concessions damaging to Western prestige and power positions. The seemingly pointless battles in which Chinese and UN troops alike continued to die were of significance only as they might contribute to breaking the resultant political and propagandist deadlocks. It was a form of "cold" war which the West found difficult to deal with.

In January 1953 Truman was succeeded in the presidency by Dwight D. Eisenhower, committed to ending the Korean War. On March 5 Josef Stalin died. Not long afterward the deadlocked negotiations at Panmunjom were resumed, and on July 27 the Korean armistice was at last signed. The relationship between these events is unclear; the end of the Korean War is shrouded in the obscurity surrounding its beginning. The death of Stalin forced drastic reappraisals of all Communist policy, and the Chinese may have doubted whether they could continue to rely on Soviet support. They may have been moved by the threat, privately conveyed by the Eisenhower administration through Indian and other channels, that if the farce at Panmunjom were not ended it would carry the war into China with atomic bombs. The war, as it was, put no light drain on China's human and economic resources, and the Chinese may have concluded that they had milked the situation of all that it was worth to them. Whatever their reasons, they in effect surrendered on the major propaganda issue (over the disposition of the prisoners of war); and, while it was never possible to convert the resulting armistice into a peace, the fighting ended. The position was stabilized along the 38th parallel frontier; and so it remained.

#### NEW INTERNATIONAL POWER STRUCTURES (1953-62)

With the death of Stalin and the signing of the Korean armistice, the cold war entered a new phase. The propaganda battles were as strident and the power plays as obstinately contested as before, but they were set now in contexts that had been changing more than was generally realized. Even Stalin in his final months had cautiously rejected the theory of inevitable war between the capitalist and Communist worlds. War might still be inevitable under capitalism, but Communist Russia could avoid it. After the Korean experience there was less faith everywhere in the efficacy of blood and firepower as solutions for the complicated problems of international politics. The position in Germany and Central Europe had been effectively stabilized; both Western and Soviet power had been rebuilt to a point at which neither could offer a fundamental challenge to the other. Fears of an imminent third world war had markedly subsided.

The nuclear arms race, with its unspeakable implications for human survival, continued to darken the world; and after the Soviet Union exploded its first multimegaton bomb (August 1953) the nuclear arsenals loomed as in themselves the greatest menace to the world society. But it was an increasingly distant menace. The Korean War had been successfully "limited"; and evidence accumulated that the powers had in fact reached a nuclear stalemate, in which not only nuclear but also conventional armaments were tending to become mere counters in the game of power rather

than actually usable instruments of power itself. The NATO alliance had never found the will or the resources to build its conventional defenses to the massive strengths envisaged in 1950, and as time went on there seemed increasingly less reason why it should do so.

**New Soviet Policy.**—The U.S.S.R. had been changing. When Nikita Khrushchev (*q.v.*), with the famous secret speech of February 1956, demolished Stalinism, the West did not immediately recognize the significance of the event. The idol had been overthrown and some of his crimes exposed; but it had been done by men deeply stained with those crimes themselves. The dictatorship was not relaxed, and there seemed no reason why the new government should not follow the same paths as the old. Actually, Russia had outgrown Stalinism. The rise of what Milovan Djilas called the "new class" of educated bureaucrats and technicians; the new technical powers of Soviet state capitalism (displayed to an astonished world when in October 1957 the Russians put the first artificial satellite in orbit); the rising demands for consumption goods flowing from the growing strength of the economy—all these were combining to render Stalinist methods obsolete. The "collective leadership" now established in the Kremlin was really collective, its members resolved that no one man should again rise to absolute power over them. The Leninist slogans of world proletarian revolution and inevitable war no longer served the policy needs of a great and consolidated modern state (as they continued, unfortunately, to serve those of the Chinese dictatorship); and the policy of "peaceful coexistence" with the capitalist world, as it was to develop under Khrushchev, was rooted more firmly in the facts of Soviet life than the West appreciated.

The Khrushchev policy has been defined (by Edward Crankshaw) as one of "physical coexistence, ideological war *à outrance*." It implied strenuous competition as well as peace, and it continued to promise the ultimate triumph of Communism everywhere. Khrushchev often used it to serve Soviet purposes that hardly seemed peaceful to the West—as in his well-known boast that "we will bury you!"—but it reflected a basic conviction that in the nuclear age a major war must be excluded; and it tended to break up the rigid confrontations of the cold war psychology. The bipolarized world of the late 1940s was itself breaking up. The de-Stalinization campaign opened up almost at once the ideological rift between Russian and Chinese Communism which was to grow, obscurely, into a major power struggle within the Communist empire of great subsequent significance. Lesser cracks were evident in the Atlantic alliance system; while there was developing a "neutralist" Afro-Asian bloc which neither of the great power systems could fully control. The Bandung (*q.v.*) Conference in the spring of 1955, initiated by Indonesia and drawing delegates from China, India, Pakistan, and other Asian and African states, led to no concrete results, but it was a portent perhaps better understood in Moscow than in Washington.

Cold war politics underwent a certain shift in emphasis. In the late 1940s Communist social revolution and native Communist parties had been openly used as instruments of Soviet conquest. The policy now being developed by the Russians (and the Chinese were to imitate them) of supporting "wars of national liberation" everywhere, whether Communist-controlled or not, was directed less toward expansion of the empire than toward enlargement of the Soviet power of political maneuver in a world now patently beyond the domination of either great power bloc. In southern Asia, the Middle East, and the Mediterranean (where Soviet interest was now reviving), the proletarian revolution and the class struggle had little meaning; what did have meaning were the driving forces of nationalism, anti-imperialism, and the "revolution of expectations." Communism, indigenous or imported, no doubt played a large part in fomenting and exploiting these forces, but the Russians did not hesitate, where it suited their political purposes, to sacrifice local Communist movements to the interests of rising non-Communist populist dictatorships, like that of Gamal Abd-al-Nasser in Egypt. These Moscow could not command but could utilize for the confounding of the West and improving the Soviet power position.

**China and Indochina.**—None of this was clearly foreseen in

1953. Winston Churchill, who may be said to have opened the cold war with his "iron curtain" speech, was the first to realize that the time might have come for ending it; and with Stalin's death he began to call for a conference "at the summit" in which the new men in Russia and in the West might together take stock of a new situation. The Eisenhower administration, still frozen in cold war concepts, did not dare take the risk. Nor was it easy to do so when Communist expansion, at last halted in Korea, was immediately to reappear in Southeast Asia. Communist China, after expelling the Nationalists in 1949, had reached the Indochinese border, across which it was soon sending weapons and support to Ho Chi Minh's guerrilla war upon the French (as well as upon those Vietnamese who responded to French rather than to Communist influence). In the spirit of the Truman Doctrine the United States had been pouring in aid for the anti-Communist cause, and in the end was largely financing the war while French, colonial, and French-led Indochinese troops did the fighting. There were many promises by the French commanders that the war could be won; but the situation became progressively more hopeless until, with the fall of the fortress of Dien Bien Phu in May 1954, it was irretrievable. (See VIETNAM: History.)

John Foster Dulles, President Eisenhower's secretary of state, was both an activist and deeply committed to the containment theory. Unfortunately, the possibilities for action were limited. In a speech in January 1954 Dulles (perhaps relying on the supposed success of the atomic threat in ending the Korean War) warned the Chinese that U.S. policy would thenceforth rely on "a great capacity to retaliate instantly by means and at places of our choosing." But the threat was of little force. It could not interrupt Chinese aid to the organized Vietminh divisions now closing on Dien Bien Phu; and when Dulles tried to organize a last-minute rescue of the fortress by air-atomic action he got no support from his allies or, in the end, from his own government. Atomic bombs were unusable in the jungles of Vietnam; and the threat, with all its limitations of "credibility," could not control such a situation.

While the fortress was in its last throes a conference of the powers had convened at Geneva with the double mission of converting the Korean armistice into a peace and of resolving the situation in Indochina. Nothing could be done about Korea. But from the conference emerged the celebrated "1954 agreement" on Indochina, in which little was in fact agreed, which the United States endorsed but did not sign, to which the government shakily established in South Vietnam was not a party, but which produced the appearance of a settlement. There was to be a cease-fire, with the contending forces withdrawing behind a demilitarized zone on the 17th parallel. Laos and Cambodia were confirmed as independent states; while the two governments in North and South Vietnam were recognized as in *de facto* control of their respective areas, with Vietnam's future to be finally decided by free elections in two years' time.

**New Treaty Systems.**—It was apparent that this really settled nothing; at best it was something less than a success for the Dulles policy of "massive retaliation." The secretary of state turned to the erection of alliance systems as barriers to further Communist expansion. The Southeast Asia Treaty Organization (*q.v.*; SEATO) was established in September 1954; while the United States encouraged (it did not join) the Baghdad Pact (*q.v.*), completed in the following year for the defense of the Middle East. The treaty systems were to prove feeble solutions to the Western problem. Designed, like their NATO prototype, primarily to meet military aggression, they had difficulty in dealing with the "war of national liberation" which had become the basis of Soviet and now of Chinese policy. By the time the paper ramparts had been erected Communist influence had already passed far beyond the boundaries they sought to define. In a sense containment was failing to contain; perhaps it was already something of an anachronism.

**Germany.**—In Europe, however, there was a marked reduction of cold war pressures. In the spring of 1955 the U.S.S.R. acquiesced in a peace treaty for Austria—long a bone of contention—guaranteeing the independence and neutralization of the coun-

try. By the summer it was possible to convene at Geneva the conference "at the summit" which Churchill had urged two years before. The attempt at a general settlement of the German question failed on the old, insoluble difficulty—neither side could permit reunification of Germany without absolute assurance that the country would never pass under the influence and control of the other. But the failure made it clear that as long as both sides excluded a major war, as they now did, there was no alternative to partition; and on that the two sides in effect agreed. At Geneva Eisenhower and Khrushchev met; both were favourably impressed. The American president contributed much to the pacific tenor of the negotiations; and if the "spirit of Geneva" was fragile, it was of real significance. Geneva could not write a peace, but it did announce a truce that marked the end of the cold war in Germany. The two Germanys were to develop thereafter under a kind of agreement to disagree on the part of the two power blocs, which was not to be interrupted for some years.

**Failures of Western "Containment."**—Outside Europe, however, the cold war went on. Here U.S. foreign policy was to some extent lamed by its obsession with Communism itself as the single great enemy. The insistence that all who were not with the West were against it made diplomacy awkward in the neutralist or uncommitted world of nationalist dictatorships, where Communism was not always as significant a factor as it seemed; and the dramatic events of 1956 were to suggest the defects of a rigid anti-Communism as the primary basis of policy. Thus when Nasser, the new military ruler in Egypt, contracted with Czechoslovakia for Communist-manufactured armaments, it was too hastily taken as a sign of his final defection to the Soviet camp. There were excited visions of Egypt as already a bridge over which Communism would pour down to the conquest of all Africa. In reprisal, Dulles secured the cancellation of the large loans the West had been offering for the construction of the high dam at Aswan. But the situation was beyond control by such rough and primitive means. President Nasser got his loans from the Soviet Union and at the same time decreed the nationalization of the Suez Canal (*q.v.*). The consequences were sensational and confusing. They included the Franco-British descent (in alliance with Israel) on Suez; a Soviet threat to use atomic bombs if this imperialist adventure were not halted; an anomalous accord between the United States and the Soviet Union against France and Britain; and the blocking of the canal by the Egyptians. With difficulty the West dug itself out of this diplomatic ruin. The canal was restored to service under complete Egyptian ownership and control; Nasser was raised to a powerful preeminence in the Arab world, while a severe strain had been put on the NATO alliance.

At almost the same time, the Hungarians rose in a major revolt against Moscow. The Russians crushed it with severity while the West looked on, powerless to intervene. Thus ended the last Western pretensions as the defenders of "freedom" against "slavery" in Central Europe. And the Soviets, while by no means reducing Egypt to a Communist satellite, had demonstrated a formidable power in Mediterranean and African affairs.

The foundations of the Baghdad Pact were at the same time seriously undermined (it was largely to collapse in 1958). The Dulles containment was proving unworkable, but the secretary laboured only the harder to bring military power to its support. In January 1957 the administration asked for and received the consent of Congress to the "Eisenhower Doctrine." This declared, with a rather curious precision, that in "the general area of the Middle East" the United States was prepared to use its armed forces on behalf of any nation "requesting such assistance against armed aggression from any country controlled by international Communism." While there was some reluctance in Congress to grant this blank check, the gesture was of little practical significance. In the following year U.S. troops were in fact landed in Lebanon (with the British cooperating in Jordan), but under circumstances that made it most improbable that they would have to do any fighting and with unclear political results.

**New Patterns of Cold War.**—Dulles, soon to succumb to a fatal illness, resigned in April 1959. That summer Khrushchev made an unexpectedly successful visit to the United States, and

he and Eisenhower conferred at Camp David (Md.) in a friendly mood. The cold war was already falling into patterns quite different from those of the grim days of ten years before. Yet the two nations were still prisoners of concepts they could not fully transcend. In the following year Khrushchev violently broke up the second summit conference, using as a pretext the bungled business of an American U-2 espionage plane shot down deep in Russian territory. His reasons are debatable, but it is probable that among them was the heavy pressure now rising against him from Peking with the growing Sino-Soviet ideological split. This factor—not even then fully understood in the West—was to add complex new dimensions to cold war politics. President Eisenhower, on his side, continued to repeat the cold war platitudes, and in his farewell address (January 1961) was still warning his countrymen that they faced “a hostile ideology, global in scope, atheistic in character, ruthless in purpose, and insidious in method.” While such concepts persisted, no peace was possible.

Nor was the world, much as it differed from that of the late 1940s, a particularly peaceable one. When the Kennedy administration took office at the beginning of 1961 there was cold war in Africa, where the Soviet, Western, and even Chinese power blocs strove for advantage amid the bloody chaos following the grant of independence to the Belgian Congo. There was continuing, if indecisive, cold war in the Arab world; the cold war in defense of Southeast Asia and Indonesia from Communism was intensifying; and the situation in Vietnam was dangerously deteriorating; while Fidel Castro's revolution in Cuba was bringing cold war to the doorstep of the United States. The nuclear arms race was more ominous in its ultimate implications, more disruptive of practical diplomacy, and more resistant to resolution than before.

Even in Germany the cold war was revived in the summer of 1961, when Khrushchev tried to force a final division of the country by threatening to conclude a separate peace with East Germany. This would have unilaterally destroyed the legal basis for the Allies' position in West Berlin, forced the West to recognize and deal directly with the East Germans, and made the partition absolute. When the West refused to yield its rights in West Berlin, the answer was the Berlin Wall, begun in August 1961 (*see* BERLIN). President Kennedy mobilized reserve divisions in the United States, but less as an actual war measure than as a sign of determination. The Russians did not insist; the West retained its position in West Berlin, but East Berlin with the rest of East Germany was now totally sealed off. The cold war went on, but it seemed that it was waged increasingly by diplomatic and political methods rather than by naked military confrontations.

**Cuba.**—It was in Cuba that the climactic crisis—itsself illustrative of the awkwardness of anti-Communist cold war concepts in the new phase of international politics—was to come. When it came to power, the Castro regime, though it included Communist elements, was chiefly of a liberal middle-class coloration. The Soviet Union had little if anything to do with its success, and U.S. policy might conceivably have dealt with it outside the cold war framework. But as Castro replaced the middle-class liberals in his administration with Communists, as he resorted to a virulent anti-Americanism to consolidate his popular power and used repressions and expropriations on the Communist pattern, he convinced U.S. opinion that this was another case of Moscow-designed infiltrative aggression of the familiar kind. This time, however, it was reaching within a hundred miles of Florida. In its final months the Eisenhower administration broke relations with Cuba, embargoed trade with the island, and began secretly to organize the anti-Castro exiles into an army of “liberation” which was to rescue the Cubans from “slavery” by fomenting a popular rising against the dictator. At the beginning of his presidency, Kennedy was forced to decide whether to cancel or go ahead with this scheme. He allowed it to proceed, under conditions which ensured its failure, and the result was the invasion fiasco in April 1961.

The invasion could not have succeeded under any conditions, as it rested on too many misconceptions as to the nature of the Castro regime, the popular attitudes toward it, and the degree

of unanimity and dedication among the exiles themselves. Anti-Communism here proved a self-defeating principle. As a result of the failure, this cis-Atlantic bastion of Communism was irrevocably established. Castro was triumphantly confirmed in his power over Cuba. To what extent he had (as he later claimed) always been a Communist may be doubtful, but he now unreservedly committed himself and his revolution to Communism. Left with Moscow as his only source of economic and political support, he was now in a position to extort from the Soviets assistance which they were at first rather slow to give. The attempted invasion, moreover, seemed to validate his contention that Cuba was in imminent peril of an armed descent by U.S. imperialism and made it difficult for the Soviet Union to refuse the military protection he demanded.

The situation was not without its embarrassment for the Kremlin. Khrushchev, committed basically to coexistence, can hardly have planned deliberately on this abrupt extension of Russian power into the western Atlantic or have wished to place Russian foreign policy in so sensitive an area at the mercy of the erratic Cuban dictator. By this time, however, the Sino-Soviet split was open and undisguised; Peking was competing with Moscow throughout the Communist world, with “peaceful coexistence” as the major point of attack. The precise motivation for the action that followed is, as always, speculative, but Khrushchev doubtless saw in his missile weapons a triple opportunity: to forestall the Chinese; to guarantee Cuba against American attack; and to improve the Soviet deterrent. In October 1962 U.S. surveillance discovered that the Soviets were installing in the island their intermediate-range ballistic missiles, capable of striking most of the more important targets in the United States. Crisis was immediate and extreme.

Yet it was hardly the war crisis that it seemed to be at the time. The success of the Soviet move depended on making the missiles operational before the United States had time to react. Once they were operational, the missiles could be evicted from the island only by a nuclear war which the United States would not risk; until they were operational they could be completed only at the cost of a nuclear war which the Russians had no intention of risking. Kennedy reacted with vigour but at the same time with restraint; and when he declared a naval “quarantine” of Cuba the situation was not unlike that which the Russians had created with the Berlin blockade in 1948. Since Khrushchev, to use a chess metaphor, had just failed to queen his pawn, he sensibly withdrew the weapons in return for an American pledge to make no military attack on Cuba and thus to leave Castro in unchallengeable power.

There was no victory, as Kennedy warned his countrymen, on either side; but there had been a firm and intelligent handling of an international crisis of which peace rather than war was the outcome. The major power issues of course remained, but to many “cold war” seemed increasingly a misnomer for the relations between the Communist and the Western democratic-capitalist worlds. In June 1963 President Kennedy, speaking at American University (Washington, D.C.), called for a “reexamination of our attitude toward the Soviet Union” and of “our attitude toward cold war” and announced a renewed effort to secure a treaty banning aboveground nuclear testing. The treaty was signed on Aug. 5. If its immediate military effects were small, it signified a major advance out of the extremes of suspicion and recrimination that had rendered abortive all previous attempts at arms control. And it gave some recognition, as well, to the fact that there were common interests underlying the rivalry of the great power blocs. When the president was assassinated in November 1963, the cold war seemed to be approaching its end. In a sense, perhaps, it had already ended, and the world was in a new stage of international politics to which the cold war concepts were now largely inapplicable. But if so, the fact was obscured by the increasingly insoluble problem of Vietnam.

#### THE LATEST PHASE (1962-67)

**Vietnam.**—The cease-fire in Vietnam in 1954 and the *de facto* partition of the country ended the formal fighting. It did not alter

Ho Chi Minh's resolve to unite the Vietnamese under Hanoi's control, nor eliminate the Communist terrorists and guerrilla groups left behind in South Vietnam. For a time these remained more or less inactive. But when the South Vietnamese government, flatly rejecting the 1954 agreements, made it clear that the promised elections neither would nor could be held, Communist pressures again began to rise. By that time the United States had assumed sole responsibility for the cold war in Indochina. The French had evacuated North Vietnam under the 1954 agreement; the United States now sped their withdrawal from South Vietnam as well, and in the spring of 1956 the last French battalions left the country. Free of the traditions of French imperialism, the United States put its diplomatic and massive economic aid directly behind the government of Ngo Dinh Diem, the "strong" and strongly anti-Communist leader who had made himself the dictator of South Vietnam. U.S. military support, however, was confined to small military advisory groups to assist in organizing and training the South Vietnamese army, which was itself expected to suppress the remaining Communists.

It was a modest and seemingly hopeful program, but before the end of the Eisenhower administration it was proving to be unworkable. While Communist terrorism mounted and the Communists expanded their control over larger and larger areas of the countryside, the inability of the Diem regime to weld an effective national resistance to Communism out of the many clashing factions and interest groups in South Vietnam became apparent. Toward the end of 1960 a Communist-dominated National Liberation Front was set up in the South, under Hanoi's inspiration, to serve as the political and administrative arm of what was now a large-scale insurrection. A year later the situation had deteriorated to a point at which it seemed necessary to back the Diem government with more than merely advisory military support, and the Kennedy administration began to send combat troops into the country. Their role was still, theoretically, only protective, supportive, and instructional; but at the time of President Kennedy's death there were some 16,000 U.S. troops in Vietnam, involved, in one way or another, more deeply in combat operations than was generally admitted.

As an instrument for winning the cold war in Vietnam the Diem regime was becoming increasingly impossible, and Washington was at least considering the desirability of "dumping Diem" when in November 1963 he was overthrown and he and his powerful brother were murdered. It did not resolve the American dilemma. South Vietnam passed into the hands of successive military dictatorships which seemed as little capable as Diem of uniting the country or infusing it with an anti-Communist determination. The new president, Lyndon B. Johnson, faced serious decisions on which he seemed to have derived little guidance from his predecessor's policies. Kennedy (according to Arthur M. Schlesinger, Jr.) had disliked the idea of U.S. troop commitments; he had apparently continued to hope that the effort could be phased out within a year or so, but felt in his final days that he had paid too little attention to Vietnam. It was a question Johnson could not avoid.

There were two possible choices. One was to accept a "neutralist" solution (for which there were many favourable factors in early 1964) in which South Vietnam, like Laos and Cambodia before it, would be offered a neutral status, the United States would withdraw, and the Saigon government would be left to fight its own political battle with Hanoi—which it would all but certainly lose. The only alternative was greatly to increase U.S. military pressure on Hanoi in the hope of forcing it to resign the contest. In January 1964 the Johnson administration chose the second course; it committed itself to "all necessary measures within our capability to prevent a Communist victory" and to placing "the fullest measure of support" behind the Saigon government. This was essentially a return to the Truman Doctrine of 1947, although under very different conditions. The theory, by no means new, that this was a pure case of "aggression" by North Vietnam toward a free and independent South Vietnamese state was elaborated to justify the policy. Behind the theory was the strategic calculation that if only the North could be induced by direct military pressure to cease its intervention the Americans and the Sai-

gon government could deal with the Communist-led insurrection in the South and with the many other appalling problems of South Vietnam.

In the spring of 1965 the Johnson administration began direct bombing attacks on North Vietnamese communications and military installations, at the same time increasing U.S. ground and air forces in South Vietnam until they reached some 200,000 men by the latter part of the year. The president launched a worldwide "peace offensive" in an effort to bring Ho Chi Minh to "negotiate," but neither the force nor the diplomacy achieved the intended result. The offer of negotiations was in effect asking Ho to negotiate himself out of South Vietnam; and since the limited force applied was insufficient to convince him that he must yield, the offer naturally had no success. It seemed to Washington that more force was the only solution, and through 1966 North Vietnam was bombed more and more heavily while U.S. troop strength in the South was steadily expanded. By early 1967 it was passing 400,000 men, often engaged in heavy combat. There appeared to be considerable diplomatic activity behind the scenes, but there were no visible signs of a negotiated peace.

**Conclusion.**—In a sense, this represented the ultimate failure of the Truman Doctrine. If the cold war was not over, its character had changed so greatly that it was hardly recognizable. The rigidly polarized international society of the late 1940s had developed into something far more complex, more flexible, and less manageable. An unyielding anti-Communism was no longer an adequate basis for Western policy, nor was it particularly successful. A doctrinaire anticapitalism and a messianic belief in world revolution no longer served many practical policy needs of the great and stabilized Soviet state. For this reason, at bottom, the Communist world had been fractured by a cold war between Russians and Chinese as savage as that which had divided Russia and the West. This Sino-Soviet power competition was leading to complex but unpredictable consequences. In Vietnam, Soviet policy seemed increasingly divided between a need to use the West as a counterweight against the Chinese, and its inability to support the West lest it validate the charges of betraying Communism which the Mao regime flung against it.

The major ills and imbalances of international society of course remained, and Communists of various persuasions continued to exploit them for various ends. The slogans and promises of Communism were still being used by nationalists and revolutionaries to achieve power; but they were perhaps losing their effect as, with power attained, the promises remained unfulfilled. The savage anti-Communist counterrevolution in Indonesia in October 1965 may have been indicative. Nasser's Egypt had not fallen under Soviet control, and Communism was hardly a driving force in renewed crisis in the Middle East; Communism was influential but anything but dominant in sub-Saharan Africa; Castro had not succeeded (if, indeed, he had ever seriously tried) in exporting Communism to the rest of Latin America. Further revolutions might lie ahead, but if so it seemed unlikely that they would serve as vehicles for Soviet—or Chinese—political power.

The world remained a difficult, turbulent, and dangerous arena, but few found in the simple concepts of cold war either a solution for its enormous problems or a protection against its perils.

**BIBLIOGRAPHY.**—D. F. Fleming, *The Cold War and Its Origins 1917-1960* (1961), is the most detailed general study; non-Communist, it is consistently critical of U.S. policy and usually gives the U.S.S.R. the benefit of the many unavoidable inferences. Even Luard (ed.), *The Cold War: a Re-appraisal* (1964), gives analyses considering the war by geographical areas. John Lukacs, *A New History of the Cold War* (1966), deals primarily with Soviet-American relations in Europe and less so in the Far East; with somewhat opinionated comparative analysis of the two societies and their people. Hugh Seton-Watson, *Neither War nor Peace: the Struggle for Power in the Postwar World* (1960), is not specifically a cold war history, dealing broadly with demographic, economic, and political forces since 1945. Comparatively few books have attempted to treat the cold war as a whole; innumerable books deal with major aspects and episodes. Some of the more useful are: W. Phillips Davison, *The Berlin Blockade: a Study in Cold War Politics* (1958); David Rees, *Korea: the Limited War* (1964); John Hatch, *A History of Postwar Africa* (1965); Edward Crankshaw, *Khrushchev, a Career* (1966); Arnold C. Brackman, *Southeast Asia's Second Front* (1966); Bernard B. Fall, *The Two Viet-Nams* (1963); Arthur M. Schlesinger, Jr., *A Thousand Days* (1965). (W. M.)

**COLE, SIR HENRY** (pseudonym FELIX SUMMERLY) (1808–1882), English public servant, art patron, and educator, intimately associated with the conscious formation of the Victorian style, was born at Bath, July 15, 1808. At the age of 15 he started clerking for the public records historian, and eventually he became assistant keeper of the public records office. Cole was involved in a multiplicity of projects, all boldly conceived and ably prosecuted. In 1845 the Society of Arts, whose new patron was Prince Albert, announced a competition which resulted in "Summerly's" tea service, manufactured by Minton's pottery works. Cole explained that its design "had as much beauty and ornament as is consistent with cheapness." The tea service sold well, and in 1847 Summerly's Art Manufactures was founded. Through it painters and sculptors designed for industries. In 1849 Cole and the painter Richard Redgrave founded the *Journal of Design and Manufactures* to promote "the germs of a style which England of the nineteenth century may call its own." In 1848 he proposed an unprecedented Great Exhibition of the Industry of All Nations. It opened in 1851 and was a triumph, featuring "art applied to industry."

The success of the Great Exhibition financed better design schooling in England. In 1852 the board of trade set up a department of practical art (later, of science and art) with Cole as secretary; in this capacity he formed the nucleus of the Victoria and Albert Museum. He was strongly attacked: Dickens thought him too functionalistic; industrialists believed they could better train their own apprentices, as before. In 1857 his school, collection, and library moved to the great complex of schools, museums, and institutes planned by Cole for Prince Albert at South Kensington. Cole then launched national training schools for cookery and music, and the grand scheme for Royal Albert Hall. In 1873 he resigned his secretaryship and in 1875 was made K.C.B.

In 1877 Ruskin attacked his work, writing "Cole at Kensington has corrupted the system of art-teaching all over England into a state of abortion and falsehood from which it will take twenty years to recover," and William Morris continued the attack. The arts and crafts movement was rising against industrial design. Before the reaction reached its crest, Cole died on April 18, 1882, but his views of design eventually prevailed. (E.R. K.)

**COLE, THOMAS** (1801–1848), U.S. painter, who was a founder of the Hudson River school and the painter of some of its most characteristic landscapes, was born at Bolton-le-Moors, Eng., on Feb. 1, 1801. In 1819 the family emigrated to the U.S., settling first in Philadelphia, Pa., and then at Steubenville, O., where Cole learned the rudiments of his profession from a wandering portrait painter named Stein. He went about the country painting portraits, but with little financial success. Moving to New York (1825), he displayed some landscapes in the window of an eating house, where they attracted the attention of the painters Asher Durand and Col. John Trumbull, who sought him out, bought his canvases, and found him patrons. From this time Cole was prosperous. A series of pictures consisting of four canvases representing "The Voyage of Life," and another series of five canvases representing "The Course of Empire," the latter now in the gallery of the New York Historical Society, were allegories, in the taste of the day, and became exceedingly popular, being reproduced in engravings with great success. The artist's romantic conception of the American landscape had an influence on his time and his fellows that was considerable. Cole spent the years 1829–32 and 1841–42 abroad, mainly in Italy, and at Florence lived with the sculptor Horatio Greenough. After 1827 he had a studio in the Catskills, which furnished the subjects of some of his canvases,

and he died at Catskill, N.Y., on Feb. 11, 1848. William Cullen Bryant wrote a eulogy for him, and Durand commemorated him in a painting. His pictures are in many public and private collections.

See E. I. Seaver, *Thomas Cole* (1949).

**COLE, TIMOTHY** (1852–1931), U.S. wood engraver, the last and best-known member of the great school of American wood engravers and probably its most distinguished master, was born in London on April 6, 1852, his family emigrating to the United States in 1858. He lost all his possessions in the Chicago fire of 1871. He moved to New York City and began to work on Scribner's magazine in 1875. He was sent abroad by his publishers in 1883 to make engravings of the old masters in European galleries. These were published with notes by Cole as *Notes to Old Italian Masters* and achieved great success. Though the advent of new mechanical methods had rendered wood engraving almost obsolete, Cole was able to continue his work, and he became one of the greatest masters of wood engraving. He died on May 17, 1931.

See A. P. and M. W. Cole, *Timothy Cole, Wood-Engraver* (1931). (H. Es.)

**COLEMANITE**, a hydrous calcium borate found in California as monoclinic crystals contains 50.9% of boron trioxide, and is an important source of commercial borates and boric acid. The principal source of borax (*q.v.*) until the 1930s, the mineral was first discovered in 1882 in Death Valley, Inyo County, Calif., and in the following year it was found in greater abundance near Daggett, in San Bernardino County, Calif., forming with other borates and borosilicates a bed in sedimentary strata of sandstones and clays. Beautifully developed crystals, up to two or three inches in length, encrust cavities in compact, white colemanite, they are colourless and transparent with brilliant lustre. There is a perfect cleavage parallel to the plane of symmetry of the crystals. Hardness is 4 to 4.5; specific gravity 2.42. The formula is  $\text{Ca}_2\text{B}_6\text{O}_{11}\cdot 5\text{H}_2\text{O}$ .

Priceite and pandermite are very similar to colemanite.

**COLENZO, JOHN WILLIAM** (1814–1883), Anglican bishop of Natal, was one of those who become famous entirely by accident. The intellectual quality of his book, *The Pentateuch Critically Examined* (1862–79), is moderate, its literary appeal negligible, and its originality doubtful, but its date and the author's episcopal dignity made it the focus of a celebrated controversy in which momentous dogmatic and legal issues were involved.

Colenso was born at St. Austell, Cornwall, Jan. 24, 1814, the son of a minor civil servant. Hesitating between the Anglican priesthood and the Nonconformist ministry, he finally settled on the former, and after ordination became rector of Fornsett St. Mary, Norfolk, in 1846. In 1853 he was made bishop of Natal. Questions put to him by Zulu converts led him, by way of mathematical argument, to doubt the historical accuracy of the Pentateuch. As it was his nature to follow out his own reasonings to their limits, he argued that any numerical discrepancies found in the book of Genesis must decisively overthrow all of the Bible.

His metropolitan, Robert Gray, bishop of Capetown, acting, as it seemed, in accordance with the charter given him by the crown, summoned Colenso to appear before him on a charge of heresy and convicted him. But on appeal the judicial committee of the privy council reversed the decision (March 20, 1865) and completely repudiated the legal assumptions on which both sides had acted. It said that the crown was powerless to appoint a bishop in a colony possessing an independent legislature, and so the royal courts could not uphold Gray's legal authority. For Colenso, the victory was only technical, for the royal supremacy, in which he firmly believed, was declared invalid in South Africa. Gray's legal authority disappeared, but his religious authority, to which Colenso had sworn allegiance, might be increased if the church in South Africa were recognized as autonomous. After some hesitation, the English bishops deposed Colenso and appointed (1869) a new bishop. But Colenso remained at his post, ministering to a dwindling band of supporters until his death in 1883. He remained to the end simple, stubborn, generous, devoted, and sublimely unaware that any type of biblical studies larger than the mathematical could exist. (A. O. C.)

THOMAS COLE. WATERCOLOUR ON IVORY BY THOMAS SEIR CUMMINGS

**COLEOPTERA**, the scientific name for the beetles, the largest order of insects. See **BEETLE**.

**COLEPEPER, JOHN COLEPEPER** (**CULPEPPER**), 1ST BARON (d. 1660), English statesman who was an influential counselor of Charles I during the Civil War and of Charles II in exile, was the only son of Sir John Colepeper of Wigsell in Sussex. Elected member for Kent in the Long parliament, he took the popular side, supporting the earl of Strafford's attainder and being appointed to the parliamentary committee of defense in Aug. 1641. He separated, however, from the popular party on the church question, opposing the proposals to abolish episcopacy and for religious union with the Scots. In the following session he opposed the militia bill and the Grand Remonstrance. On Jan. 2, 1642, he joined the king's supporters, taking office as chancellor of the exchequer, but he disapproved of Charles's attempted arrest of five members of the commons (Jan. 4). He delivered the king's final proposals for peace at the bar of the commons on Aug. 25, 1642. In the Oxford parliament he advised concessions to secure peace. He received a peerage in 1644.

Colepeper was sent with Edward Hyde (afterward earl of Clarendon) in charge of the prince of Wales to the west in March 1645 and, after Charles's final defeat, went with the prince to the Scilly Isles and thence to France (1646). In 1648 he accompanied the prince on his unsuccessful naval expedition and returned with him to The Hague. After Charles I's execution, he pressed upon Charles II the acceptance of the Scots' proposals. Sent to Russia in 1650, he obtained from the tsar a loan of 20,000 rubles. The treaty between Oliver Cromwell and Cardinal Mazarin in Aug. 1654 compelled Colepeper to leave France for Flanders.

At the Restoration he returned to England, but survived only a few weeks, dying on June 11, 1660. He was succeeded in turn by his three sons, the title becoming extinct in 1725.

(S. R. Br.)

**COLERAINE**, a seaport, market town and municipal borough of County Londonderry, Northern Ireland, on the Bann river 4 mi. from its mouth and 27 mi. E.N.E. of Londonderry. Pop. (1961) 11,912. The main town on the east bank radiates from a central square, the Diamond, but a suburb extends west of the river across the bridge. There were once a priory, a monastery and a castle at Coleraine. The modern town of Coleraine (Cuil Rathain, "fern corner") owes its foundation to the companies of the City of London who undertook the colonization of County Londonderry under the scheme for the Plantation of Ulster, operating through the Honourable the Irish society, founded in 1610. The society still owns property and confers benefits on the district. Industries include linen spinning and weaving, shirt and collar making, distilling, bacon and ham curing, salmon fishing and manufacture of milk products and automatic numbering machines. Coleraine is a road and rail junction. The harbour accommodates small vessels.

(Hu. S.)

**COLERIDGE, (DAVID) HARTLEY** (1796-1849), English poet whose wayward genius achieved its most sustained expression in sonnets of great skill and sweetness, was born on Sept. 19, 1796, at Kingsdown, Bristol. The eldest son of Samuel Taylor Coleridge, he spent his childhood at Greta hall, near Keswick, Cumberland, alarming and delighting his family and the Southys and Wordsworths by his mental agility and the "exquisite wildness" which caused his father and Wordsworth to address poems to him prophetic in their forebodings. At school at Ambleside (1808-14), he was ridiculed for his oddity but admired for his power to carry his schoolfellows into his own intensely imagined world of fantasy. He entered Merton college, Oxford, in 1815, and in 1819 gained an Oriel fellowship, but forfeited it after a year by intemperance and lack of application.

In 1820 he began literary hackwork in London, and contributed to the *London Magazine*, but again instability cut short a promising career and he returned to teach at his old school. In 1832 he moved to Leeds, to work for a young publisher, F. E. Bingley. Bingley's bankruptcy terminated the contract and in 1833 Coleridge returned to Grasmere, where, with two short intervals of teaching at Sedburgh, he lived until his death on Jan. 6, 1849. He became a legendary figure among the dalesmen, who loved

"Lile (little) Hartley" for his simple friendliness, were proud of his brilliance and pitied his excesses which, although they made him prematurely old, never destroyed either his sweetness of temperament or his intellectual ability.

Both the defects and the qualities of Hartley Coleridge's character are reflected in his writings. There are many brilliant beginnings, but few are sustained. His sonnets are sensitive, revealing acute observation and the self-knowledge which caused him to describe himself as "a thriftless prodigal of smiles and tears." His unfinished lyric drama, *Prometheus*, shows intellectual power. A scholarly edition of Massinger and Ford and his critical essays are marked by sane judgment and masterly use of the illuminating, discursive aside. His prose recalls Lamb in its learned humour and unexpectedness, and reveals a personality equally lovable though fatally flawed.

**BIBLIOGRAPHY.**—Bingley published *Poems* (1833); *Essays and Marginalia and Poems*, with a memoir by his brother Derwent, appeared posthumously (1851). His *Letters* were ed. by G. E. and E. L. Griggs (1937). See also E. L. Griggs, *Hartley Coleridge* (1929); H. Hartman, *Hartley Coleridge* (1931).

**COLERIDGE, JOHN DUKE COLERIDGE**, 1ST BARON (1820-1894), lord chief justice of England, was the eldest son of Sir John Taylor Coleridge. He was born at Heath's Court, Ottery St. Mary, on Dec. 3, 1820, and was educated at Eton and Balliol college, Oxford, of which he was a scholar. He was called to the bar in 1846, went the western circuit, and in 1865 was returned as a Liberal member for Exeter. In 1868 when the Liberals returned to power Coleridge was made first solicitor general and then (1871) attorney general.

His arrival in parliament strengthened the body of Oxford men who had attacked the legislation that kept the university under ecclesiastical domination. In addition to his own talents he carried weight with the clerically minded section as the eldest son of Sir John Taylor Coleridge; as the godson of John Keble; and as the great-nephew of the man who was an indirect cause of the Anglican revival of 1833—Samuel Taylor Coleridge, the poet.

The Tichborne trial of 1871-73 (see **TICHBORNE CLAIMANT**), involving a contested inheritance, was the most conspicuous feature of Coleridge's later years at the bar and taxed his powers as an advocate to the uttermost, though he was assisted by Charles (afterward Lord) Bowen (*q.v.*). In Nov. 1873 Coleridge succeeded Sir W. Bovill as chief justice of the common pleas, and in 1874 was raised to the peerage. In 1880 he was made lord chief justice.

In jury cases his quickness in apprehending facts and his lucidity in arranging them were remarkable. He was not one of the most learned of lawyers, but he was a great deal more learned than many thought, and as an ecclesiastical lawyer had few superiors. His fault—natural in one who had been so successful as an advocate—was that of being too prone to take one side, and he allowed political or personal prepossessions to colour the tone of his remarks from the bench. Latterly his health failed, and he became somewhat indolent.

Coleridge's addresses and papers have not been published. One of the best and most characteristic of the man was his inaugural address to the Philosophical institution at Edinburgh in 1870; another was a paper on Wordsworth (1873). He was an exceptionally good letter writer. He was sarcastic and critical, and at times oversensitive. But his strongest characteristics were love of liberty and justice. By birth and connection Conservative, he was a Liberal by conviction. He died in London on June 14, 1894.

His *Life and Correspondence*, ed. by E. H. Coleridge, was published in 2 vol. in 1904; see further Edward Manson, *Builders of Our Law* (1904); for the history of the Coleridge family see Lord Coleridge, *The Story of a Devonshire House* (1907).

**COLERIDGE, SAMUEL TAYLOR** (1772-1834), English poet, lecturer, journalist, and critic of literature, theology, philosophy and society. Known as the author of *The Ancient Mariner*, or as an opium addict, or as the friend of Wordsworth or as Carlyle's "Oracle of Highgate," he has been obscured rather than comprehended by vague and imperfect epithets.

**Early Years, School and University.**—The distortions of fact and interpretation, some of them self-inflicted, that were to

pursue him begin with the time and place of his birth. He was born at Ottery St. Mary, Devon, on Oct. 21, 1772. The general opinion about the place has often been erroneous; it was the old King's school in Ottery St. Mary, not the vicarage. He himself was wrong about the date; he lived under the impression that he was a day and a year older than he was and suffered guiltily all his life from procrastination and an oppressive sense of wasted time. His father, John Coleridge, was headmaster of the King's school and later vicar of Ottery St. Mary. Described by S. T. C.—so he often styled himself—as “a perfect Parson Adams,” he was also a scholar. Coleridge was said to resemble him physically and he had certain intellectual affinities with him. By him the child's mind was “early accustomed to the Vast”; i.e., the starry heavens and Platonic theology. His sudden death when Coleridge was seven was, according to Coleridge's autobiographical letters to Thomas Poole, what would now be called a traumatic experience. S. T. C. was the youngest of ten children, nine boys and one girl, but far from being the spoiled darling of the household, he was solitary, moody and, as he said, “a tall-tale,” temperamentally alien from his brothers. Like them, his mother appears to have been ambitious in practical ways for her sons, but not especially tender toward her least conventional and most imaginative child.

In his ninth year Coleridge entered Christ's Hospital, the noteworthy facts of his school days there being, in addition to loneliness and possibly the beginnings of ill-health, his friendship with Charles Lamb and the acute and strenuous instruction of James Bowyer in English composition, described in *Biographia Literaria*. There too began his first love affair, with Mary Evans, broken off, unhappily and with misunderstanding, in 1794.

In Oct. 1791 Coleridge entered Jesus college, Cambridge, as a sizar (as Wordsworth had entered St. John's) and went down in 1794 without a degree. The most notorious episode of his college life was his runaway enlistment in the 15th light dragoons, in Dec. 1793, out of embarrassment over college debts, and his return to Cambridge, bought out of the army by his family, in April 1794. More important facts of his undergraduate days were: his winning the Browne gold medal in 1792 for a Greek ode on the slave trade; his reputation for conversation, sociability and a lively interest in contemporary thought; his ardent support of William Frend in his trial by the university authorities for his liberal *Peace and Union* pamphlet in 1793; and his meeting during his last Cambridge long vacation in 1794 with Robert Southey, and their scheme for founding a utopian or “pantisocratic” community on the banks of the Susquehanna river in America.

**Life with Southey, Marriage to Sara Fricker and Meeting With Wordsworth.**—For the first half of 1795 Coleridge and Southey lived together in Bristol, writing, planning and lecturing. Southey's defection from pantisocracy led to a quarrel which lasted for about a year from Sept. 1795. However, 1795 saw them both giving public lectures, more controversial than profitable, Southey's on historical, Coleridge's on political and theological subjects. *The Plot Discovered* and *Conciones ad Populum* were at once published, probably as evidence for the defense in case it were needed against a threatened charge of treason. (These were reprinted by Sara Coleridge in *Essays on His Own Times*, 1850.) Six theological lectures were given and exist in incomplete reports. Of a course of six political lectures announced on “A Comparative View of the English Rebellion Under Charles the First and the French Revolution,” there are no known records.

For all this mundane if idealistic activity, it is perhaps worthy of note that the youthful Coleridge was already in 1797 referred to as a “bard” (so nicknamed a year later by the villagers of Nether Stowey) in verses addressed to him in *Felix Farley's Bristol Journal*. His friend Joseph Hucks, with whom he had taken a walking trip in Wales in 1794, in a volume of poems (1798) two years before his early death, addressed some “Lines to S. T. Coleridge.” They show clearly the community of idealistic interests of the young men of this period: protests against the condition of the poor, opposition to the war against France, and attacks on the slave trade, as well as sentiments for solitude, moonlight, ruins and the like; they also suggest Coleridge's intellectual leadership.

The most unfortunate and almost the sole consequence of the

plan for an ideal community (necessarily based on a group of married couples) was Coleridge's imprudent and apparently half-reluctant marriage on Oct. 4, 1795, to Sara Fricker, sister of Edith Fricker, later Mrs. Robert Southey. It appears from some reminiscences dictated in old age to her daughter that Sara Fricker at one time expected Southey to marry her, a fact which might help account for Southey's pressure on Coleridge to carry through a rash and immediately regretted proposal of marriage and for Sara's acrimonious comparisons of S. T. C. with Southey as husband, which, among other temperamental and practical difficulties from both sides, eventually made the Coleridge marriage a failure.

Coleridge's youthful reputation as poet was based on a few short poems in the *Cambridge Intelligencer* and the *Morning Post*, on the play *The Fall of Robespierre* (written in Aug. and published in Oct. 1794) and on other poems, such as “Religious Musings,” circulated among friends. His literary and social interests in Bristol introduced him to the bookseller and publisher Joseph Cottle and, in autumn 1795, to William Wordsworth.

From the time of his meeting with Wordsworth and his marriage to Sara Fricker, Coleridge was beset by a continual conflict which in a sense these events represented: the struggle to realize and release his creative abilities; and the struggle with what he called “bread and cheese,” the effort to be a practical husband, father and professional man. The conflict, acute enough in the economic conditions of the wars against France, was not lessened on the professional literary side by the shifting intellectual currents and values of the period after the French Revolution. Coleridge's personal problem was also exacerbated, to an extent unrealized either by him or his circle of family and friends, by what the autopsy after his death in July 1834 showed to be a progressive disease going back at least to this time: a disease of heart and lungs which made him appear neurotic or hypochondriacal all his life, i.e., a greatly enlarged heart and liver and cysts on the lungs. This physical state, usually referred to in connection with his later life and death, may well have been one of the governing facts of Coleridge's life from about 1795.

**First Collection of Poems and Literary Collaboration With Wordsworth.**—For the first four years of his marriage, the practical problem was met partly by newspaper contributions and book reviews, the full extent of which is only now being discovered. On his own initiative a periodical called the *Watchman*, largely written by him with some articles by Thomas Poole and a few others, was published from March to May 1796, but it ended with the tenth number, a financial disaster as Coleridge's domestic responsibilities at this time included not only his wife and child but her mother and brother. The crisis was smoothed over with help from Poole, Josiah Wade, George Dyer and perhaps others, and by Cottle's publication in April of *Poems on Various Subjects*, Coleridge's first collection of poems. At the close of 1796 he wrote and published separately his *Ode to the Departing Year*. On the last day of the year, the Coleridges moved to Nether Stowey to be near his friend and benefactor, the public-spirited tanner Thomas Poole. The year 1797 saw a second edition of the *Poems*, “To which are now added Poems of Charles Lamb and Charles Lloyd.” By Coleridge's own account, 1797 also saw the beginning of “The Ancient Mariner” and the writing of “Kubla Khan” at Brimstone farm on the northwest coast of Somerset close to Culbone church; the ending of “Kubla Khan” was lost forever by the interruption of the unknown but now notorious “person from Porlock” who called on Coleridge there. Coleridge's 1797 date has been disputed by Elisabeth Schneider but accepted on probably stronger grounds by E. K. Chambers, H. M. Margoliouth and others. *Osorio*, a tragedy, was also written in 1797 but was rejected for Drury Lane theatre by Sheridan, whose jeers and failure to return the manuscript became a cause of grievance.

That autumn Coleridge also met Thomas Wedgwood, as a result of whose friendship he received from Thomas and his brother Josiah early in 1798 an annuity of £150 a year on condition that he give up the idea of becoming a Unitarian minister and devote himself to writing. Hazlitt, who met Coleridge at Shrewsbury when he preached there, has described Coleridge as preacher in his essay “My First Acquaintance With Poets.” Coleridge was much in-

volved with Unitarians at this time and sympathetic to their rational theological and liberal political views, but he was undoubtedly relieved to be free of close subscription to any particular dogma and a confined way of life. The relief from pressing financial worries and the increasingly close intimacy with the Wordsworths released a flow of some of his best poems, "Frost at Midnight," the completion of "The Ancient Mariner," "Christabel" (part 1), "Fears in Solitude," "The Nightingale" and *France, An Ode* (or *The Recantation*, as it was once called). In Sept. 1798 the *Lyrical Ballads* was published by Cottle, an anonymous volume opening with "The Ancient Mariner" and ending with Wordsworth's "Tintern Abbey"; there were three other poems by Coleridge, 19 by Wordsworth.

The close literary collaboration, one of the most far-reaching and influential in the history of English literature, though based on a friendship that lasted about 15 years, was relatively brief. In Sept. 1798 Coleridge and the Wordsworths—William and his sister Dorothy—went to Germany to learn the language and something of the literature and philosophy, the Wordsworths to Goslar and Coleridge to Ratzeburg and to Göttingen, where he matriculated at the university in Feb. 1799. He appears to have spent an energetic few months learning the language and attending lectures on various subjects. He was also said to be "the life of the party" socially, speaking German badly but volubly. In April he had word from Sara of the death of their second son Berkeley. In July he returned to England and Stowey and renewed his broken friendship with Southey by a walking trip in Devon. In Oct. 1799, with Cottle, he went north at Wordsworth's invitation and for the first time saw the Lake district, with John and William Wordsworth. It was on this journey, at Sockburn in Yorkshire, that he first met Sara Hutchinson (whose sister Mary was later to marry Wordsworth). The love of Coleridge and Sara from the beginning was deep and painful, for Coleridge, who had long realized the imperfection of his marriage to the other Sara, did not believe in divorce. He returned to London as leader writer for the *Morning Post* and to begin a translation of Schiller's *Wallenstein* from a manuscript made available by Schiller.

**Leader Writer for the "Morning Post"; Life at Keswick.**—In spite of the stresses of his personal life, his *Morning Post* contributions of this—as of later periods—are vigorous journalism of a high order, opposing the Pitt ministry and the war against France and advocating liberal and moderate yet anti-Jacobin views. He reported parliamentary debates and wrote some skilful and cogent pieces; e.g., on Grenville and on Pitt.

The translation of *Wallenstein* he found a "soul-wasting" business, and in April, the moment it was finished, he left London for the north, paying his first visit to Dorothy and William Wordsworth in Dove cottage. He then went to Stowey and Bristol to visit his friends there and to join Mrs. Coleridge and his son Hartley. After considerable conflict about whether to settle in the south near Poole or in the north near Wordsworth, the issue was decided by Dorothy Wordsworth's practicality in finding a house for him at Keswick; the Coleridges settled in Greta hall in July 1800.

The description "lake poet" is thus for Coleridge a misnomer. Actually his periods in the lakes were short, a broken one from July 1800 to Jan. 1804, and another shorter stay from Aug. 1808 to Oct. 1810. The decision to live there may have been one of his most serious errors. Mrs. Coleridge was unhappy, separated from her family and acquaintances; Coleridge himself found the climate too cold and wet for his asthmatic and rheumatic condition; and even the society of the Wordsworths 16 mi. away in Grasmere was less consoling than having Poole next door, especially after Aug. 1800 when Charles Lloyd, mischief-maker among them all and satirist of Coleridge in his novel *Edmund Oliver* (1798), settled at Ambleside and by mere proximity disrupted the peace of Coleridge's visits to Dove cottage.

Another and perhaps chief element in his unhappiness, frustration and self-disappointment, was his sense of the loss of creative imaginative power by continual comparison of himself as poet with Wordsworth. The contrast between his own misery and inertia, and Wordsworth's increasing power and happiness was symbolized

in Wordsworth's publication over his own name of the second edition of the *Lyrical Ballads* (1800) without (as had been intended) the addition of "Christabel"; in 1802 his marriage to Sara Hutchinson's sister Mary sharpened the contrast. A tour of Scotland in 1803 undertaken by Wordsworth, Dorothy and Coleridge showed a few premonitory signs of difficulties between them. They separated after 15 days and Coleridge walked with almost disastrous energy 263 mi. in eight days, apparently making an effort to conquer the opium habit by violent physical exertion.

**Stay in Malta and Italy.**—At the end of 1803 he decided that a warmer, drier climate was essential to his health (already breathing had become frequently difficult) and felt also that he must escape from the whole complex of emotional conflicts represented by Greta hall and Dove cottage, Keswick and Grasmere. His self-awareness has been insufficiently known, as the notebooks now demonstrate. In a painful and lonely state of mind he sailed in 1804 for Malta, one result of the semitropical voyage being some interesting revisions and additions to "The Ancient Mariner." Arriving in May, he became in July private secretary to the acting governor, Alexander Ball, and in Jan. 1805, on the death of the public secretary, he assumed that office temporarily. This is one of the least-known, and in practical activity one of the busiest, periods in Coleridge's life, in literary respects one of the least productive. Yet Coleridge in six months had learned sufficient Italian to understand even the rapidly spoken Italian of angry seamen in dispute: he had mastered the problems of Maltese and Sicilian economy so far as to prepare reports for Ball and to support him in the view that Malta had strategic importance to Britain not only as a military base but as the potential granary storehouse of the Mediterranean. He also wrote (with Charles Pasley) on the advisability of Britain's cultivating Egypt rather than relying on the West Indies for cotton, sugar, fruits, etc. His summer vacation (Aug. to Nov. 1804) in Sicily gave him a wide insight into Mediterranean problems, took him twice up Etna and acquainted him with a number of U.S. naval officers, including the distinguished Stephen Decatur and Comdr. Edward Preble, whose ships were stationed at Malta and Sicily during the American-Tripolitanian war. Coleridge's sympathy with the American Revolution and American views was extended and developed by the experiences and acquaintances of this period and especially by his friendship with the American painter Washington Allston, whom he met in Rome a few months later, in Jan. 1806.

The work as acting public secretary in Malta detained him there until Sept. 1805 when the new public secretary, Edmund Chapman, arrived. Worsening health, boredom with the narrow social confines of Malta, loneliness in the entire absence of literary or any intimate society and the sense of a profitless dead-end existence made him anxious to return home. There he felt he might usefully advocate the cause of the Maltese and a more aggressive British policy in the Mediterranean, especially in regard to Egypt. He had hoped to be franked home overland as a government courier, but the end of the year 1805 which saw the battles of Ulm (Oct. 19) and Austerlitz (Dec. 2) was a poor time for English travelers in Europe. On leaving Sicily he went first to Naples where he had an introduction from Alexander Ball to Hugh Elliot, the British ambassador to the court of Naples, whence he took a mysterious journey lasting two or three weeks into the depths of Calabria. He returned to Naples just in time to hear of Nelson's death at Trafalgar. In Naples he stayed some weeks with the English painter George Wallis, through whom he may have met other English artists when he reached Rome on Dec. 31, 1805; one of these, a young student named William Russell, from Exeter, gave him some much-needed financial help. In Rome he met the artist colony, of whom Washington Allston was one of the more important members, and various other interesting persons, such as Ludwig Tieck (with whom he was to resume a connection years later at Highgate), the Prussian ambassador Wilhelm von Humboldt and his brother Alexander, the scientist. As in Germany, so in Malta, Sicily and Italy, Coleridge wherever he went attracted or was attracted to an eminent literary and intellectual society and appears to have been at ease in what, it seems, was his natural social milieu; in this geniality he was very different from Wordsworth, the reserved northerner.

Allston painted a portrait of Coleridge at this time and though it was never finished it is one of the most attractive and one of the best. With Allston he saw many works of art though unfortunately the records of his comments are few, possibly from the loss of many of his papers on the homeward journey. In turn, he exerted a considerable influence on Allston's own work and on his views of literature and painting, as Allston's lectures and letters testify.

It is some indication of the scale of warfare in those days that on being advised to quit Rome to avoid the French, Coleridge went about 30 mi. into the country to stay with Allston in his villa at Olevano Romano. From there he returned to Rome and left on May 18 with young Russell for Florence, Pisa and Leghorn. A story about his having left Rome hurriedly in Cardinal Fesch's carriage appears to have been garbled or largely invented. It is true that he had advance warning to leave because of the approaching French army, but he did not leave suddenly, nor by stealth in a carriage: whether or not he was on Napoleon's black list because of his articles in the *Morning Post* and whether he was warned of it by some emissary of the pope, as he stated in *Biographia Literaria*, is not corroborated. In the atmosphere of the times there is no reason to doubt the possibility. In Florence he was seriously ill, and until June 23, when he finally embarked at Leghorn in a U.S. ship, he was much preoccupied with the difficulties of finding a passage home. This may account for the fact that there are almost no records of his response to Florentine art, though he was frequently to refer later to the "Triumph of Death" murals at Pisa, but in a moralistic rather than an aesthetic context.

The journey homeward took 39 days, to which were added 17 days at the end for quarantine. He had been acutely ill on the ship and landed at Stangate creek in Kent on Aug. 17, 1806, about two years and four months after his departure from Portsmouth, very much the worse physically, financially and emotionally for his severe, lonely experience. On the positive side, the chief gains were a certain cosmopolitanism of sympathy and enlarged views of English foreign affairs, as well as an enhanced though critical patriotism, which appear in his later writings.

**Years of Depression, 1806-1816.**—Coleridge's life may be viewed as a composite of several careers (poet, preacher, lecturer, playwright, journalist, reviewer and miscellaneous writer), all broken off from time to time, but a recurring pattern appears in almost every decade from 1794 to 1834. In 1806 on his return to England, therefore, he returned to several of these occupations. He procrastinated in returning to Keswick; he was undoubtedly loath to return to Mrs. Coleridge and the tensions of Greta Hall and to face the Dove cottage circle with his sense of failure and deterioration, but at the same time he was also very short of money, perhaps even for the fare, and was trying to find work with the foreign office and then with newspapers. An article for the *Courier* on Charles James Fox, recently dead, appears to have been proposed but not written. He began rewriting *Osorio*, and was invited by the Royal Institution to give a course of lectures, to which he felt unequal. He visited Thomas and Catherine Clarkson at Bury St. Edmunds and went north with them via Cambridge where he saw Richard Porson again (who may have introduced him years before to William Godwin); here he paid a small debt and was shocked by the gambling at Newmarket. He arrived on Oct. 26 at Kendal, where the Wordsworths and Sara Hutchinson were alarmed by his unhealthy appearance. Two weeks in Keswick were enough to convince him that the incompatibility of their temperaments made separation from Mrs. Coleridge inevitable. In December he took his son Hartley with him to Coleorton, the country house of Sir George Beaumont, where the Wordsworths and Sara Hutchinson were spending some weeks. The old easy atmosphere was, however, not recaptured. Coleridge grew jealous of what he interpreted, in an unhappy episode and in Sara Hutchinson's attitude, as a preference for Wordsworth and a diminution of affection for him. It was one of many blows, exaggerated in effect by illness and despair.

The year 1807 was almost a total loss in Coleridge's life so far as productivity is an indication of vitality. It was further vitiated by the reduction of the Wedgwood annuity (the whole of which for

years had gone to Mrs. Coleridge and her mother) and by inability to form any clear plan of work or settle on any fixed abode. He lived in this year chiefly with Poole, with Bristol friends and with John and Mary Morgan and Mrs. Morgan's sister, Charlotte Brent; with the three last he appears to have reproduced a faint facsimile of his relation to the Wordsworth household. Longman offered to publish two volumes of poems which did not materialize. A Greek grammar and vocabulary was also abortive. In this summer the earl of Egmont, greatly impressed with Coleridge's learning and eloquence, proposed that he do a theological work, and it is clear that he was thinking and talking a good deal about religion at this time and affirming and confirming his transition from a unitarian to a trinitarian position. But no fruit matured in writing. His suggestion that he should follow his nephew Edward as a master at the Ottery school was not taken up by his family. There was an additional and more rending contretemps over a proposed visit with Mrs. Coleridge and the children (precipitately in Bristol for the purpose) to Ottery, to gloss over and get approval for the separation. In August he had met the young Thomas De Quincey (*q.v.*), hitherto an unknown idolater of Coleridge and Wordsworth; in November, through Cottle, De Quincey made him a barely disguised anonymous gift of £300 and took Mrs. Coleridge back to Keswick. It now seems fairly clear that out of gratitude for hospitality, Coleridge lent or gave most of the £300 to Morgan, who was threatened with imprisonment for debt.

Yet Coleridge began 1807, barren though the year was for him, with the composition in January of the lines "To William Wordsworth" and ended it in December in London preparing his lectures for the Royal Institution series on poetry. The lectures ran from January to June, a course much broken by illness and frequently very disappointing in quality.

The years after the return from Malta were years of uncertainty of every sort, personal and domestic, financial, professional and physical. Health deteriorated until Coleridge himself more than once considered the possibility of imminent death, a mental institution or laying his whole case before a doctor for treatment. In Dec. 1808 the death of his old friend, the physician Thomas Beddoes, was a blow to the third plan.

By that time he had sufficiently mastered his health temporarily to inaugurate his second private periodical, *The Friend*. Twenty-eight numbers were published in spite of unimaginable mistakes in practical judgment, difficulties of every sort and the almost unanimous discouragement of friends. From Sept. 1808 till March 1810 he had the assistance of Sara Hutchinson, who took much of it at his dictation. They were both staying with the Wordsworths at Allon Bank. But though the atmosphere was better for a time than it had been in 1807, all was not well. The Wordsworths feared for Sara Hutchinson's health and encouraged her to go to her brother Thomas in Wales for a rest. Without her support, and in the face of this overt expression of tension and disapproval, and also confronted by the evident financial and practical obstacles to continuing, Coleridge abandoned *The Friend* and went first to Keswick and then in October to London, in search of work.

On arrival in London at the home of Basil Montagu there was precipitated what has come to be known as the Wordsworth quarrel. The immediate basis was a report to Coleridge by Montagu of unkind remarks by Wordsworth about Coleridge as a guest; without judging, one can easily see in it Coleridge's inordinate vulnerability and loneliness, Wordsworth's diminished tolerance and lack of full understanding and Montagu's crass tactlessness. The breach was outwardly patched over chiefly by the efforts of Lamb and Crabb Robinson, but not until 1812; and relations were never restored to the old intimacy, probably because the emotional and intellectual "dyspathy"—a Coleridge word—was partly real; possibly it has been understated in view of the much more important positive and creative sympathy in their early association.

The years from 1810 to 1815 were surely among the most unhappy of Coleridge's life, yet in them there were sporadic bursts of activity, some highly successful. In 1811, in addition to writing for the *Courier*, he gave his second course of lectures, from Nov. 1811 to Jan. 1812 (on Shakespeare and Milton) attended by

Byron, Samuel Rogers and Crabb Robinson. He paid a visit to the lakes in the early spring of 1812, reissued *The Friend* in a single volume with a few revisions and in May-June delivered his third course of lectures, again on drama, chiefly Shakespeare. By the end of the year he had rewritten *Osorio* as *Remorse*, for which Lamb wrote a prologue. It had the unusually successful run at Drury Lane of 20 nights in Jan. 1813 and ran to four editions before the end of the year. From the spring of 1813 for the best part of the next three years, Coleridge lived with various friends in the west country, in and around Bristol, where he lectured again on Shakespeare (six lectures) and twice on education, and in April 1814 gave another course on a variety of subjects; he may have given one or two other sets of lectures. But he was ill and forced to cancel and reannounce, and newspaper reports give but an incomplete picture of events.

The most remarkable literary fact of his next year is that he began to dictate the *Biographia Literaria* to John Morgan, who, as midwife to this remarkable work, should be more known and respected than he has been. That Morgan was able to extract it at this time was a real triumph, for Coleridge was in the depths of despair about his opium addiction, now scarcely concealed; about his financial position, especially in relation to schooling and college for his sons Hartley and Derwent; and about feelings of his moral decline on almost every front. In addition—another mark of that intense inner vitality which very often mystified his friends—by the end of the year he was considering a publication, at Byron's urging, of "Christabel" and "Kubla Khan."

**Last Years at Highgate, 1816-1834.**—The result of all this pushing and pulling by encouraging friends was a flow of notable publications soon after his establishment at Highgate in April 1816: *Christabel* (three ed. in 1816); *The Statesman's Manual*; or *the Bible the Best Guide to Political Skill and Foresight* (1816); in 1817 a second *Lay Sermon*; *Sibylline Leaves* (the fourth and much enlarged collection of his poems); *Biographia Literaria* (two volumes originally intended as a preface to his collected poems); *Israel's Lament* (for Princess Charlotte), the translation of a poem in Hebrew by Hyman Hurwitz; and *Zapolya, A Christmas Tale*. The tide of productivity continued to flow in 1818 with a new edition of *The Friend*, enlarged significantly by the essay "On Method"; he also gave two successful courses of literary lectures. In 1818 Coleridge also produced some of his clearest and best prose in his pamphlets on behalf of Sir Robert Peel's Factory acts to protect children against exploitation in the cotton factories.

From here onward the story is one in which sorrows and disappointments loom large again, above all, Hartley's dismissal from his fellowship at Oriel college, Oxford, chiefly for uncontrolled drinking and consequent inefficiency. This was a severe blow, undoubtedly producing in his father self-recriminations worse than any public embarrassment.

It was in 1819 that an accidental meeting with John Keats took place in Millfield lane, Highgate; the evident respect and admiration of younger men as diverse as Keats, Edward Irving, Thomas Allsop, Joseph Henry Green, Julius Hare, John Sterling, F. D. Maurice and Coleridge's nephews—Edward, Henry Nelson and John Taylor Coleridge—and such recognition as Lamb's moving dedication of his *Works* (1818), were gratifications that helped to counterbalance Hazlitt's attacks in the *Edinburgh Review* and the *Examiner*. In 1822 Henry Nelson Coleridge began making notes for his *Table Talk*. There were new poems germinating and old half-forgotten ones returning to attention, notably the lovely, poignant "Youth and Age," and other shorter lyrics that deserve to be better known than they generally are. As late as 1828 "The Garden of Boccaccio" was written.

In 1824 Coleridge was elected a royal associate of the Royal Society of Literature, for which he prepared a lecture on "The 'Prometheus' of Aeschylus." This election brought him an annual stipend of 100 guineas a year. Life began to feel and to be more benign to him, though Hartley's weaknesses and Derwent's unsettled views were worries; and it transpired that his third child, Sara, was in love with her first cousin, Henry Nelson Coleridge, and that the marriage, which Coleridge could accept but never fully approve, would take place—as it did in 1829.

In 1825 *Aids to Reflection* was published, the work by which Coleridge became best known in American transcendentalist circles and which perhaps did most to fix him as the "Oracle of Highgate," in the public mind; it ran to two English editions and one American by 1831. There is an appropriateness about the fact that Hazlitt's essay in *The Spirit of the Age*, describing the kind of oracle that Coleridge had been for him in his youth, appeared in this same year. In 1827 Coleridge had a serious illness which aged him noticeably, yet in 1828 the fifth collected edition of his poems was published by Pickering in three volumes that included the plays. It is some indication of his prestige and reputation; though it was no financial help, that the 300 copies were sold out by Oct. 1828. A new and much corrected edition appeared in 1829. *The Constitution of Church and State*, Coleridge's last prose work in his lifetime, appeared in two editions—the second considerably augmented—in 1830. In 1834 the third Pickering edition of the *Poetical Works* appeared in time for Coleridge to see it before his final illness and death at Highgate on July 25, 1834.

**Reputation and Influence.**—The impression of the last years, in fact of the Highgate period generally, is of a growing mellowness, of a gracious and gentle manner with rays here and there of the old ebullience, now somewhat softened by time and made serene by the tenderness with which the Gillmans devoted themselves to caring for him. There were occasional lapses from grace at Highgate in the matter of opium, but in the main the addiction was under control, if not completely conquered until the 1830s. Highgate was a haven and in more than its physical features provided a kind of eminence which both fitted and fostered his powers. Wordsworth said that though he had known many great men, Coleridge was the only "wonderful" man he had ever known. Among the wonders were not only the abilities displayed in the Quantock hills in the composition of "The Ancient Mariner," "Christabel" (part 1) and "Kubla Khan" but the resilience and energy displayed in the recovery in his last years. And perhaps no less remarkable is the in-between period, a wide valley of humiliation in which nevertheless some of the best of the criticism was written or spoken.

Coleridge has been given more numerous and various reputations than perhaps any other English poet, the broad bases of agreement being—though the causes assigned are very disparate—that his powers were never fully realized in his works. Hazlitt called him "an eagle dallying with the wind," Shelley "a hooded eagle among blinking owls." John Stuart Mill, whose essay is still one of the best introductions to him, thought him, with Bentham, one of the two great "seminal" minds of his age. Thomas Love Peacock, satirizing him as Mr. Flosky in *Nightmare Abbey*, described him as living "in the midst of that visionary world in which nothing is but what is not." Opinion has shifted between such extremes as Mill's and Peacock's, but no serious historian of English thought has been able to disregard him, whether antipathetic generally, like Leslie Stephen, H. W. Garrod, and Irving Babbitt, or appreciative, as, for example, George Saintsbury, I. A. Richards, Herbert Read, Kenneth Burke and M. H. Abrams, to select but a few. On the whole, the positive attitude came to prevail.

Coleridge's stature as a poet has not been in doubt; even here his reputation has been enhanced by new attention to poems less known than the great three—"The Ancient Mariner," "Christabel," and "Kubla Khan." "The Ancient Mariner" remains, however, pre-eminent among poems in English, as a tale. Both as narrative and poem it displays those rare qualities, characteristic of Coleridge's poetry: swiftness and clarity; a constant movement of thought and feeling—outward to the natural world of sights, sounds and tangibles, suggested with piercing clarity, and inward to the inescapable enclosure of horrors and fears, vivid or half-realized but starkly expressed; the close observation of both the minute and the panoramic, the minuscule insect and the tropical ocean where "at one stride comes the dark" or a harbour where "the bay was white with silent light"; and, on another level, the insight into the particular and the sweeping sense of the Infinite and the One. And all is controlled by so firm an architecture and so free-flowing a metre as to seem effortless.

His pre-eminence as a critic is almost equally accepted, though

not everyone would go so far as Saintsbury in his *The History of English Criticism* (1911), "So then there abide these three, Aristotle, Longinus, and Coleridge . . . we cannot quite say he is the greatest of the three . . . but his range is necessarily wider." But there are many for whom he is the most important English critic, chiefly because he raised central questions about criticism itself, its methods and philosophical basis. Yet in this field where he is pre-eminent, he is blamed or credited, according to the propounder, on the one hand with confusing life and literature and leading criticism in the direction of the moral absolutism of such critics as A. C. Bradley, and, on the other, in a glossary of the "new criticism," receives at the least verbal homage of being treated as its fountainhead; his influence on the criticism of the third to the sixth decades of the 20th century, from I. A. Richards onward, is very marked, and increasingly so. Briefly, it depends on his view of literature as requiring that marriage of emotion and thought be described as imagination; of the poem as essentially not a fixity but a continuing dynamic process in poet and reader, and as such, capable of incorporating truths and materials pertaining to any area of life and of articulating the less-than-conscious levels of experience—in fact, universal, and open to reinterpretation in successive ages. The function of criticism itself he conceived to be the lifting of all these elements into awareness, not the prescribing or even describing of rules that can neither be adequately formulated by the critic nor adhered to by the writer, but rather the elucidation of what he called "the principles of grammar, logic and psychology," i.e., the basic elements of the writer's medium (language), of his instrument (the human mind) and of human capacities and needs—the arc of the writer's limits and purposes.

For his journalism, it has been claimed that he set a new standard by being both more faithful and more original and imaginative than others; yet though he was valued by his editors for contributions that increased the circulation of their papers, he was notoriously unreliable with copy and left a trail of unfulfilled commitments behind him. As a social critic he is denounced by some as the youthful, renegade radical turned Tory and opponent of the Reform bill; to others he is the Tory who never forgot his radical conviction of the primacy of social over political considerations and whose thinking was a force among early Christian socialists. Theologically he has been claimed and attacked both by high church Tractarians and liberal Anglicans of the broad church movement, and has been credited with restoring the church to a sense of its real function and with introducing the "higher criticism." Philosophically to him has been attributed the first introduction of German transcendentalism into England by an Englishman and by others his knowledge of German philosophy has been derided or denied. By some he is regarded as more specifically a Platonist of the school of Plotinus and again, "before Kierkegaard was born, Coleridge had already formulated the existentialist philosophy" (Herbert Read). The followers of Freud and Jung both see in his work premonitions of the sort of psychological analysis they favour.

It will be seen that Coleridge has been looked upon as the founder or forerunner of enough antipodal theories to make one suspicious of attempts to assign him to any one school or any one school to him. Vagueness or a careless eclecticism cannot necessarily be deduced from this, but rather the vitality of his thought, and, contrary to some firmly entrenched opinion, its inquiring rather than dogmatic tendency.

In all his roles, as poet, social critic, literary critic, theologian, psychologist, Coleridge displays a continuous concern with the creative principle as central to the human being and, anagogically, to the universe. The imagination is a paradigm of the Logos. But it is also a psychological term for an observable form of human activity. Coleridge combines a sense of the universal and ideal with an acute observation of the particular and the sensory. In the poems this interplay of larger and smaller forces, of objective and subjective, of the generic and the individual, is to be seen, for example, in "The Ancient Mariner" in the close relation between the elements and the mariner's inner states; similarly in "Dejection," "Frost at Midnight" and many others. In social criticism it means an insistence on seeing "The constitution of

Church and state according to the idea of each," and the need of individuals to be treated as persons. In literary criticism it means critical attention to the powers of the human mind and the limits of criticism generally and particular attention specifically to the text and to the meanings of each single word in the text. In biblical criticism it means an apprehension of the Bible as a storehouse of ineffable truths and also as close a critical attention to it, textually and historically, as to any other literary document. Psychologically it means the awareness of the human psyche as a whole and a dismissal of 18th-century faculty psychology, along with much subtle analysis of mental states, including a clear anticipation of Freud in observations of varying degrees of consciousness, including the concept of the unconscious mind.

In this last connection it should be pointed out finally that one of Coleridge's chief contributions is the strenuousness with which he followed the Socratic injunction, "Know thyself." His failures here, as in other respects, are obvious; but the attempts are notable and are becoming more fully known with the publication of more and more manuscript remains—letters, notebooks, marginalia, etc. As time goes on, the judgments of an earlier day are modified. The opium taking, the procrastination, the domestic difficulties are seen to have their physiological and otherwise understandable causes, not innate but circumstantial and psychological. Here is found one of the most capacious imaginations in the history of English literature and thought articulating, in spite of complex frustrations and sometimes with extraordinary beauty and a kind of power given to very few human beings, the myriad aspects of the human condition without isolating them from one another. He enriches the awareness, both in breadth and depth, of any reader who reads him in his own spirit of inquiry. See also references under "Coleridge, Samuel Taylor" in the Index volume.

**BIBLIOGRAPHY.**—For a bibliography of Coleridge see *Cambridge Bibliography of English Literature*, vol. iii (1940) and supplement, vol. v, pp. 556–565 (1957).

A complete edition of his works, in progress in 1961, was to appear in approximately 20 vol. published by Rupert Hart-Davis, London, and the Bollingen foundation, New York. By the early 1960s there was no adequate biography. The first full-length one by James Dykes Campbell (1894) is superseded by much new information, and that by E. K. Chambers (1938) is too antagonistic and intellectually limited to be sound, even factually, on personal matters, though it provides a compressed and useful compendium of the more strictly external information.

Of the poems the standard edition is that of E. H. Coleridge, 2 vol. (1912). Of the *Biographia Literaria* the best editions are those by Sara Coleridge, 2 vol. (1847), the 2-vol. ed. by J. Shawcross (1907) and the Everyman edition by George Watson (1956; rev. 1960). The remainder of the literary criticism is most conveniently found, but not by any means complete, in *Coleridge's Shakespearean Criticism*, 2 vol. (1930) and *Coleridge's Miscellaneous Criticism* (1936), both ed. by T. M. Rayson. Some of the political writings were collected by Sara Coleridge in *Essays on His Own Times*, 3 vol. (1850), and these and others have been selected by R. J. White in *The Political Thought of Samuel Taylor Coleridge* (1938) and have received a clear and dispassionate commentary by John Colmer in *Coleridge, Critic of Society* (1959).

The philosophical materials, much of which were long unpublished, are produced in various forms—lectures, marginalia, fragments—in *The Philosophical Lectures of Samuel Taylor Coleridge*, ed. by Kathleen Coburn (1949); A. D. Snyder, *Coleridge on Logic and Learning* (1929), and E. H. Nidecker's publication of numerous marginalia on German philosophers in the *Revue de littérature comparée* (1927–32). J. H. Muirhead's *Coleridge as Philosopher* (1930) has a strong 19th-century idealist bias.

Among the monographs on Coleridge on a variety of subjects, the following make interesting contributions to knowledge of Coleridge, and some incorporate new material: John Livingston Lowes, *The Road to Xanadu* (2nd ed., 1930; rev. 1951); Stephen Potter, *Coleridge and S. T. C.* (1935); I. A. Richards, *Coleridge on Imagination* (1934; 2nd ed. 1950); Kathleen Coburn, *Inquiring Spirit: a New Presentation of Coleridge from His Published and Unpublished Prose Writings* (1951); E. Schneider, *Coleridge, Opium and Kubla Khan* (1953); R. Florence Brinkley, *Coleridge on the 17th Century* (1955); J. Beer, *Coleridge the Visionary* (1959); the *Collected Letters*, in six volumes, ed. by E. L. Griggs, began appearing in 1956; the *Notebooks*, ed. by Kathleen Coburn, in 1957. *A Concordance to the Poetry of Samuel Taylor Coleridge*, ed. by Sister E. Logan, was published privately (1940). The marginalia are to be collected but by 1961 were to be found largely in periodical articles (see *Cambridge Bibliography of English Literature*, vol. v).

**COLERIDGE, SARA** (1802–1852), English writer, the only daughter of Samuel Taylor Coleridge, a scholar in her own right,

editor of her father's works and also the author of verses for children. She was born on Dec. 22, 1802, at Keswick, Cumberland, where Coleridge lived with his brother-in-law, Robert Southey. Coleridge was seldom at home and Southey was the chief influence on Sara's early years. In fact she did not see her father between 1812 and 1822, when she visited him at Highgate with her mother. Thereafter his influence developed rapidly. In 1822 she translated from the Latin Martin Dobrizhoffer's *An Account of the Abipones*, with which her father was delighted. In 1825 she followed it with a translation of the *Memoirs of the Chevalier Bayard*.

In 1829 she married her cousin, Henry Nelson Coleridge. For her children she wrote *Pretty Lessons in Verse for Good Children* (1834) and *Phantasmion* (1837), a fairy story with some delightful lyrics. She thus anticipated a minor branch of Victorian literature. When her husband died in 1843 he left unfinished the task of editing Coleridge's works. She continued it, and made several contributions to Coleridgean studies, notably an "Essay on Rationalism" appended to the 5th edition of *Aids to Reflection* (1843), and a supplement and exhaustive notes to the 2nd edition of *Biographia Literaria* (1847). At the end of her life she formed many literary friendships, her comments on them being preserved in *Memoir and Letters of Sara Coleridge* (1873), by her daughter Edith. She died in London on May 3, 1852.

See E. L. Griggs: *Coleridge Fille* (1940). (P. M. Y.)

**COLERIDGE-TAYLOR, SAMUEL** (1875-1912), a British composer who enjoyed considerable acclaim in the early years of the 20th century, was born in London on Aug. 15, 1875. His father, distressed by his inability to progress as a physician—through apparent racial prejudice—deserted his son and English wife and returned to his native west Africa. At the age of five Samuel began playing the violin and joined the choir of a Presbyterian church in Croydon, where H. A. Walters guided his progress and arranged his admittance to the Royal College of Music in 1890.

Coleridge-Taylor studied composition there with C. V. Stanford. While still a student he published some anthems, but his creative gifts were more apparent in various colourful instrumental works. In 1896 he became conductor of an amateur orchestra in Croydon and began teaching, peripatetic conducting, recital work and adjudication of music festivals in order to support his wife and two children. He persisted as composer and was an early success at the Gloucester festival—to which he was recommended by Edward Elgar—with an orchestral *Ballade* (1898), which was followed by his outstanding achievement, the Longfellow trilogy of *Hiawatha's Wedding Feast* (1898), *The Death of Minnehaha* (1899) and *Hiawatha's Departure* (1900). In these and numerous other works including incidental music, choral works and a violin concerto (1911), influences from Dvořák, Tchaikovsky and Grieg appear, along with a spontaneity derived from appreciation of negro folk music. In this respect Coleridge-Taylor was a pioneer. He was well received in the United States (1904, 1906, 1910), and enjoyed the respect of H. T. Burleigh, Horatio Parker and G. W. Chadwick. He died at Croydon, Surrey, on Sept. 1, 1912.

**COLET, JOHN** (1466?-1519), English theologian and founder of St. Paul's school in his native London, was educated at Oxford, probably at Magdalen college, and then spent three years traveling and studying in France and Italy. Returning to England c. 1496, he was ordained. He lectured at Oxford on the Pauline Epistles, his exegesis of which was so original that he attracted large audiences. He was appointed dean of St. Paul's cathedral in 1504. His unsuccessful attempt to reform the cathedral chapter was partially compensated by his foundation and endowment of St. Paul's school (c. 1509). He died at Sheen, Surrey, Sept. 16, 1519.

In collaboration with Erasmus, Thomas More, William Grocyn and Thomas Linacre, Colet enthusiastically promoted the new learning of the Renaissance. His devotion to the ethos of Christian humanism expressed itself in several ways: in the statutes of

St. Paul's school he insisted that the classics be taught; for the most part he expounded the Scriptures in a critical manner; he exulted at the publication of Erasmus' edition of the Greek New Testament (1516); he adopted as his philosophy the Neoplatonism of Plotinus, the "Pseudo-Dionysius" and the contemporary Florentines Marsilio Ficino and Giovanni Pico della Mirandola; and finally he inveighed against the ecclesiastical abuses of his day. Grieved and angry because the church fell far short of the pristine purity of the apostolic age, he so fearlessly denounced the sins of the clergy that he incurred the suspicion of heresy. Yet, although he anticipated the Protestant reformers in his attack on corruption, the evidence suggests that he would have opposed any breach with Rome.

Colet's works, most of which remained unpublished until the 19th-century editions of J. H. Lupton (1867-76), include commentaries on Romans and Corinthians and treatises on the sacraments, the church and the *Hierarchies* of Pseudo-Dionysius. His statutes for St. Paul's school and a Latin grammar written for the school are printed in Lupton's *Life of John Colet* (1909).

See E. W. Hunt, *Dean Colet and His Theology* (1956).

(E. W. Hu.)

**COLET, LOUISE** (née REVOIL) (1810-1876), French poet and novelist who was a close friend of Alfred de Musset, Gustave Flaubert and Victor Hugo. Born on March 9, 1810, at Aix-en-Provence, in 1834 she went to Paris where her salon became a haunt of many writers and artists. With Flaubert she had a stormy relationship, lasting eight years, which was responsible for his splendid *Lettres* addressed to "la Muse." After her violent estrangement from him, she avenged herself in a novel entitled *Lui* (1859), which caused a sensation at the time. Her other works include *Fleurs du Midi* (1836), *Penseuses* (1839) and *La Jeunesse de Goethe* (1839) for which, through the agency of Victor Cousin, she received Academy prizes and a pension. She died in Paris on March 9, 1876.

See Gérard Gailly, *Les Véhémences de Louise Colet* (1934) and J. F. Jackson, *Louise Colet et ses amis littéraires* (1937). (R. DL.)

**COLETTE, SAINT** (1381-1447), reformer of the Poor Clares, founder of the Colettine Poor Clares, was the daughter of a carpenter, named Boillet, at the monastery of Corbie, France. Orphaned at 17, she entered the third order of St. Francis, living in a hermitage given her by the abbot of Corbie. Her austere way of life drew many visitors; when they ceased to come, she lived in seclusion for three years. Charged by St. Francis in a vision to restore the Poor Clares to the severity of their rule, she undertook the task in 1406. Perceiving the need of strong ecclesiastical authority, she at once visited the antipope Benedict XIII, who took her into the Poor Clares and made her abbess over all the houses she might found or reform. Despite initial opposition, her reform made rapid headway in Savoy, Burgundy, France, Flanders and Spain and spread more rapidly after her death. She was canonized in 1807, and her feast day is March 6. (J. N. G.)

**COLETTE, SIDONIE GABRIELLE** (1873-1954), the most famous French woman writer of her day, member of the Belgian Royal Academy and the first woman member of the French Académie Goncourt, was born on Jan. 28, 1873, at St. Sauveur-en-Puisaye, Burgundy. She spent her early life there and although she lived many years in Paris she remained a countrywoman at heart, with the sights and sounds of the countryside always in her mind.

At the age of 20 she married Henry Gauthier-Villars, a bohemian adventurer 14 years older than herself. He had literary ability but his talent was chiefly employed in organizing the work of ghost writers to meet his constant need for money. At his instigation she wrote her four "Claudine" stories, a series of fictionalized reminiscences about an uninhibited young heroine, published under his pen name of "Willy" (1900-03). She described this collaboration in *Mes Apprentissages* (1936).

In 1904 she published her first independent work, *Dialogues de bêtes*, under the signature "Colette Willy." These sketches of her cat and dog showed the remarkable knowledge of the ways of animals which characterized her work, particularly *La Paix chez les bêtes* (1916) and *Prisons et paradis* (1932). Her gift for describing nature was seen in the lyrical prose of *Les Vrilles de la*

*Vigne* (1908). Her feeling for words and for rhythm and cadence seemed as acute as her understanding of the world of birds, beasts and flowers: she could exactly convey whatever the senses could record.

After divorcing her husband in 1906 she began a music-hall career. In 1907 her first independent novel appeared, *La Retraite sentimentale*. *La Vagabonde* (1910) and its sequel *L'Entrave* (1913) reflected her stage experiences, as did *L'Envers du music hall* (1913). From this work onward, she signed her books "Colette."

In 1912 she married Henry de Jouvenel, politician and proprietor-editor of *Le Matin*; a daughter was born in 1913. After the outbreak of World War I she wrote for *Le Matin* and subsequently for many other periodicals. Her journalism included dramatic criticism, sketches of personalities, law-court reporting and chronicles of fashion; her dramatic criticism was reprinted in *La Jumelle noire*, 4 vol. (1934-38).

A series of notable novels began with *Chéri* (1920). In collaboration with Léopold Marchand, she turned *Chéri* into a play and took the part of Léa, the heroine, in three productions between 1925 and 1927. A fairy opera, *L'Enfant et les Sortilèges*, with her libretto and Maurice Ravel's music, was given its first performance in 1925.

Much of her work was autobiographical, notably *La Maison de Claudine* (1922) and *Sido* (1929). Here she wonderfully recaptured the days of her childhood and drew an affectionate, observant portrait of her mother, which is probably her finest character study.

Her later novels included *Le Blé en herbe* (1923), *La Naissance du jour* (1928), *La Chatte* (1933), *Duo* (1934), *Le Toutoumier* (1939) and *Julie de Carneilhan* (1941). She tended to write stories rather shorter than the average full-length novel. This desire for conciseness is brilliantly exemplified in her last stories, *Le Képi* (1943) and *Gigi* (1944). Several of her works were successfully filmed, *Gigi* outstanding among them.

Unlike many of her contemporaries, Colette was committed to no doctrine or ideology, nor did she discuss the problems and dilemmas of the 20th century. She depicts human nature in its instinctive reactions and feelings, the pleasures of physical sensation and especially the sadness or disillusion that love may bring.

She divorced Henry de Jouvenel in 1924 and in 1935 married Maurice Goudekot, a writer. This marriage brought much happiness, interrupted by her husband's imprisonment at the hands of the Gestapo in World War II. During her last years Colette wrote reminiscences and descriptive works which gained her new renown, particularly *L'Étoile vespérale* (1947) and *Le Fanal bleu* (1949). From 1949 onward she was increasingly crippled by arthritis and tied to her flat in the Palais-Royal, surrounded by the warm regard of the people of Paris; she became a legendary figure. In 1953 she was made grand officer of the Legion of Honour. She died in Paris, Aug. 3, 1954, and was accorded official honours by the French government at her funeral.

Chauvière, *Colette* (1931); Yves Gandon, *Le Démon du style* (1938); *Colette par elle-même*, ed. by Germaine Beaumont and A. Parinaud (1951); Margaret Crosland, *Madame Colette: a Provincial in Paris* (1954); Jean Cocteau, *Colette* (1955); Maria Le Hardouin, *Colette* (1956). Nearly all her works are available in English translations. (S. C. Gb.)

**COLFAX, SCHUYLER** (1823-1885), U.S. congressman and vice-president of the United States (1869 to 1873), was born in New York city on March 23, 1823. After an elementary education in the New York public schools, he moved with his mother and stepfather in 1836 to Indiana, where he became interested in journalism and politics. Combining the two interests, he founded in 1845 the *St. Joseph Valley Register*, which became one of the most influential papers in the state during the 18 years of his editorship.

Not a man of fixed political principles, nor one who made any lasting contribution to national life, Colfax shifted easily from Whiggery, to Know-Nothingism (which he later falsely denied), to the Anti-Nebraska (later Republican) party, which elected him to congress in 1854. There he served from 1855 to 1869, the last

BY COURTESY OF THE LIBRARY OF CONGRESS

SCHUYLER COLFAX

six years as the agreeable and popular speaker of the house of representatives. A leader in the radical wing of the Republican party during the Reconstruction era, he favoured extending the suffrage to the Negro and disfranchising those who had prominently served in the Confederacy. In 1868 he was nominated for the vice-presidency on the Republican ticket headed by U. S. Grant and was elected. He was not re-nominated in 1872, however, because a congressional investigation had implicated him, along with other politicians, in corrupt transactions with the Crédit Mobilier of America. He had also accepted in 1868, as a campaign contribution, a gift of \$4,000

from a contractor who had supplied the government with envelopes while Colfax was chairman of the post office committee of the house of representatives.

At the end of his term Colfax returned to private life under a cloud, and during the remainder of his life he earned a livelihood by delivering popular lectures. He died at Mankato, Minn., on Jan. 13, 1885.

See Willard H. Smith, *Schuyler Colfax* (1952). (D. Do.)

**COLIC**, a term in medicine for any paroxysmal pain. There is a tendency, however, to restrict use of the word to a pain produced by the contraction of the muscular walls of any hollow organ of which the aperture has become more or less occluded, temporarily or otherwise. For renal and biliary colic, see URINARY SYSTEM; GALL BLADDER, BILIARY TRACT AND LIVER, DISEASES OF.

In infants, usually those who are bottle-fed, intestinal colic is common and is shown by the drawing up of the infant's legs, restlessness and continuous cries. Colic may accompany any form of enteritis or an intestinal malignant growth, and certain forms of influenza (q.v.). It is also a common symptom of lead poisoning.

**COLIGNY, GASPARD DE CHÂTILLON**, COMTE DE (1519-1572), admiral of France and leader of the Huguenots during the first half of the Wars of Religion, was born at Châtillon-sur-Loing on Feb. 16, 1519. He was the son of Gaspard de Coligny, known as the marshal de Châtillon (d. 1522), and of Louise de Montmorency, sister of the constable of France, Anne de Montmorency. His brothers, Odet, cardinal de Châtillon, and François, seigneur d'Andelot, also played an important part in the first period of the wars. At the age of 22, Coligny came to court and there formed a friendship with François de Lorraine, 2nd duc de Guise. In 1544 he served in the Italian campaign and was knighted on the battlefield of Cerisoles. After the death of Francis I (1547), his uncle Montmorency returned to favour, and Coligny was appointed colonel general of the infantry. In this capacity he drew up the ordinances (promulgated in 1551) designed to regulate the conduct of soldiers and to protect the civil population from their outrages. He was made admiral of France in 1552. In 1557 he courageously defended St. Quentin against the Spaniards but had at last to surrender. He was then held prisoner at Sluis till 1559.

Already in 1555 Coligny had favoured the plan for sending Huguenots to establish, in safety, the colony of "Antarctic France" in Brazil. When he returned from captivity he had, under his brother d'Andelot's influence, become a Huguenot himself (Calvin's first letter to him is dated Sept. 4, 1558). Thenceforward he was the protector of his coreligionaries in France. After Henry II's death (1559), he demanded religious toleration, gaining the support of Michel de l'Hospital and Catherine de Médicis. At the assembly of notables (1560) there was open hostility between him and the Guise family.

However, when the civil wars began (1562), Coligny took up arms only on the insistence of his wife, Charlotte de Laval (d.

1568), and he was always ready to negotiate. Though not a great strategist, he was able to initiate a war of movement instead of position warfare, and his *sang-froid* and tenacity made him "the hero of misfortune."

In 1569 the death of the first prince de Condé, at Jarnac, left him the sole experienced leader of the Huguenots. Victorious at La Roche-Abeille (June 1569) but repulsed before Poitiers and severely defeated at Moncontour (Oct. 1569), he rallied an army in southern France and advanced as far as the upper Seine valley, thus obtaining for the Huguenots the advantageous peace of St. Germain (Aug. 1570).

Returning to court in 1571, Coligny grew rapidly in favour with Charles IX. To distract the French from civil war and to remove the king from the influence of the Guises, he proposed to attack Spanish Flanders with a joint Catholic and Huguenot army to be commanded by Charles in person. Catherine de Médicis, however, did not want a conflict with Spain and feared for her own influence over the king.

On Aug. 22, 1572, in Paris, Coligny was wounded by a shot from an arquebus. The king visited him and ordered an inquiry into the attempted assassination. Then Catherine persuaded Charles to forestall a rising of the Huguenots by ordering the deaths of all their leaders, and the massacre of St. Bartholomew's Day began.

At dawn on Aug. 24, mercenaries of Henry de Guise attacked Coligny at his house, struck blow after blow and finally threw him, still living, from a window. Mutilated by the mob, his body was hanged on the gibbet at Montfaucon.

Coligny's six children by his first marriage include Louise (1555–1620), who was married in 1571 to Charles de Téligny (d. 1572) and in 1583 to William the Silent, prince of Orange (d. 1584); and François (1557–1591), admiral of Guienne (1589), who served Henry IV. By his second marriage (1571), to Jacqueline d'Entremonts, Coligny had a posthumous daughter, Béatrix.

(1926–34); S. L. England, *The Massacre of Saint Bartholomew* (1938); F. Delage, *La Troisième Guerre de religion* (1953); K. Manoury, *Die Schlachten Colignys* (1957); J. de Pablo, "Die Hand am Degen," *Bull. der hug. Kirche* (1961–62). (L. Ma.)

**COLIIDAE**, a family of sparrow-sized, but long-tailed, African birds, often called mousebirds from their habit of creeping about in trees. See COLY.

**COLIJN, HENDRIKUS** (1869–1944), Dutch statesman, the most important figure in Dutch politics in the 1930s, was born at Haarlemmer meer on June 22, 1869. He served in the colonial army during the period of the Atjeh war (1895–1904) in the north of Sumatra, where later as a civil administrator he organized government services and rubber plantations. Back in the Netherlands in 1909 he started a political career as a member of parliament for the orthodox Calvinist Antirevolutionary party. From 1911 to 1913 he was war minister; in 1914 he became director of the Royal Dutch Oil company (Shell). From 1922 onward, after the death of Abraham Kuyper, he led the Antirevolutionary party and edited its daily newspaper *De Standaard*. As minister of finance (1923–25) he began a policy of curtailing government expenditure, the navy excepted, and of reassessing the guilder on the gold standard. As prime minister (1933–39) he attempted to adapt his country's economy to the world crisis by the devaluation of the guilder and the increase of agricultural exports. Finally, because of disagreement over his policy of economy, he had to drop the Roman Catholic party from his coalition cabinet. On July 22, 1939, he attempted to govern without them, but had to resign after five days. Having remained in the Netherlands as editor of *De Standaard*, Colijn was arrested by the Germans in July 1941. He died in a German concentration camp on Sept. 16, 1944.

See B. Offringa, ed., *Een Groot Vaderlander: Dr. H. Colijn* (1947). (F. DE J.)

**COLIMA**, a small Pacific coast state of Mexico, lying between Jalisco on the northwest and north, and Michoacán on the east. Including the Revilla Gigedo Islands, its area is 2,106 sq.mi. Pop. (1960) 164,450. The larger part of its territory is within the nar-

row, flat coastal plain, beyond which it rises toward the northeast into the foothills of the Sierra Madre. It is drained by the Armeria and Coahuayana rivers and their affluents, which are largely used for irrigation.

The soil is generally fertile and productive, but lack of transportation facilities has been a serious obstacle. The dry and rainy seasons are sharply defined. The climate is hot, humid and malarious, becoming drier and more healthful on the higher mountain slopes of the interior.

Stock raising is an important industry in the higher parts of the state. Agriculture is the principal occupation, the more important products being sugar, rice, Indian corn, palm oil and coffee. The "Caracolillo" coffee, produced on the slopes of the mountains culminating in the volcano of Colima, is reputed the best in Mexico.

There are important mineral deposits in the state, including iron, copper and lead. In 1907 a branch of the Mexican Central railway (now National Railways of Mexico) was completed between Guadalajara and the capital, Colima city, and continues to the port city of Manzanillo, pop. (1960) 19,950, a thriving Pacific coast resort with bathing beaches, coconut palms and fishing facilities. Cuyutlán, immediately south of Manzanillo, is the centre of a large salt-producing industry.

The Revilla Gigedo Islands lie about 500 mi. off the coast. In 1957 an outpost was established on Socorro, the largest island, 24 mi. long by an average of 9 mi. wide. Trees were planted for timber and fruit. The expedition found about 8,000 sheep on the island, the residue of a temporary Australian settlement of the middle 1800s. The islands are rich in sulfur, fish and guano and have excellent pasturage. (J. A. Cw.)

**COLIMA**, capital city of Colima state, Mex., 570 mi. W. by S. of Mexico City, near the Pacific coast. Pop. (1960) 43,518; altitude 1,548 ft. About 30 mi. N.E., the volcano of Colima in the state of Jalisco rises to an elevation of 12,992 ft. The most westerly of Mexico's active volcanoes, its eruption in 1941 caused great loss of life. A well-built, attractive city, Colima enjoys a moderately cool and healthful climate.

Founded in 1522 by Gonzalo de Sandoval, Colima has played a minor part in Mexican history because of its inaccessibility. Now connected by rail as well as paved highway to the port of Manzanillo and interior points, Colima's industry centres upon the processing of local agricultural products such as cotton, rice, corn, tobacco, fruits and sugar cane, together with salt refining, alcohol distilling and the manufacture of shoes and leather goods. (H. R. Hv.)

**COLLAR**, something worn or fastened around the neck, particularly a band of linen, lace or other material, which, under various shapes at different periods, has been worn by men and women to serve as a completion or finish to the neckband of a garment (see DRESS). It is also a chain, worn as a personal ornament, a badge of livery, a symbol of office or as part of the insignia of an order of knighthood. The word also is applied to that part of the draft harness of a horse that fits over the animal's neck, to which the traces are attached (see HARNESS AND SADDLERY), and to a circular piece of metal passed around the joints of a rod or pipe, to prevent movement or to make the joint steam- or watertight.

**COLLARDS** (*Brassica oleracea acephala*) bears the same botanical name as kale, from which it differs only in leaf characters. The leaves form a large, prolific rosette like a cabbage plant that is approaching the formation of a head but never forms a true head. The larger leaves may be removed for use singly as the stem elongates, or the entire rosette may be harvested. The plant is a prolific source of nutritionally important minerals and vitamins A and C. It is widely adapted, easily grown, and is probably the least exacting of any of the crucifers in its requirements for successful seed production. When fully grown the plants may be left unprotected in the garden, through the winter, in the southern half of the U.S. See CABBAGE. (V. R. B.)

**COLLATERAL**, in banking and in law, a term used to describe the security which a borrower surrenders as a pledge to guarantee the repayment of his loan. If the borrower defaults, the lender has the right to sell the collateral and retain the amount due on the debt. (See BANKING: Practice of Banking; MORTGAGE;

**SALE OF GOODS.)** The term is also used in the law of succession to describe the relationship between persons descended from the same ancestor but in a different line, such as aunts, uncles and cousins (see **CONSANGUINITY**). Collateral is also used to describe an attack on judicial proceedings which is based on some incidental grounds which do not test the real merits of the complaint.

(E. G. S.)

**COLLE, RAFFAELLO DAL** (RAFFAELLINO) (c. 1495–1566), Italian painter whose claim to distinction is that he was one of the executants of the frescoes planned by Raphael's group in the Vatican Loggia and the Room of Constantine, was born at Borgo San Sepolcro about 1495. Allegedly a pupil of Raphael, he was more probably a pupil of Raphael's chief assistant Giulio Romano (q.v.). He assisted Giulio, as he had Raphael, at Mantua in 1524 and, from 1536, helped in large projects of Giorgio Vasari at Florence and Rome. To attempt to sort his work from others is a puzzling task. His independent paintings, executed at Borgo San Sepolcro, are of a much lower provincial standard and give no clue. According to Vasari he died there, Nov. 17, 1566.

See A. Venturi, *Storia dell'arte italiana*, vol. ix, part 5, pp. 607–620 (1932); F. Hartt, *Giulio Romano* (1958). (C. Gr.)

**COLLECTIVISM** as a political theory first emerged in the 18th century as a reaction to individualism (q.v.). Whereas individualistic social theories and systems emphasize the priority of the individual and his rights, collectivistic theories and systems emphasize the priority of the community and its rights. Society is conceived in individualistic political theories as having no reality in itself and no interests or aims apart from those of the individuals composing it. In collectivistic theories individuals are conceived as having no real being apart from society. Whereas individualism found typical expression in political theory in the writings of the English philosopher Locke, collectivism found early expression in Rousseau's *Social Contract* (1762) and in the writings of the German philosopher Hegel.

According to the French philosopher Rousseau, the individual finds his true being and freedom only in submission to the "general will" (*volonté générale*) of society, which will is not the sum of particular wills but what remains when private interests cancel each other. "The general will," Rousseau declares, "is always right and tends to the public advantage." For practical purposes he suggests that the "general will" is ascertained by the vote of the majority. In Hegel's political philosophy the individual is conceived as realizing his true being and freedom only in unqualified submission to the laws and institutions of the national state since, in Hegelian thought, the state is the highest and most perfect embodiment of social morality.

Hegel describes the national state as the actualization of the ethical Idea, "the absolute power on earth" and "the march of God in the world." The state includes but transcends the purposes of individuals and is a living entity with a will, purpose and interests of its own. In the philosophy of Karl Marx, which was derived in part from the philosophy of Hegel, it is explicitly stated that "It is not men's consciousness which determines their being, but their social being which determines their consciousness" (*A Contribution to the Critique of Political Economy*, preface). In collectivistic theories and systems the individual acquires significance only by virtue of his membership in some social entity such as a nation, a class or a race.

In an economic context the word collectivism is used to describe any theory or system which favours governmental ownership of the means of economic production, distribution and exchange. But it is sometimes used to describe any system which favours extensive governmental regulation of the economy. In this context collectivism represents a reaction to economic individualism (*laissez-faire* capitalism), the classic justification of which is found in the writings of the Scottish political economist Adam Smith.

In reaction to individualistic political and economic theories and systems, collectivism finds expression in the contemporary world in four principal types of social systems ranging from liberal democratic to despotic totalitarian: social democracy, socialism, communism and fascism. The least collectivistic is social democracy, which aims at reducing the inequities produced by the capitalistic

system and the abuses of unrestrained competition, not by abolishing the private ownership of the means of production but by extending governmental regulation over the economy, by seeking to redistribute the wealth of society by tax legislation and by instituting various schemes of social welfare and insurance. Advocates of social democracy often speak of a "planned economy" and the "welfare state." Social democracy was anticipated in the United States in the writings of Lester Frank Ward and found practical expression in the so-called New and Fair Deals. It found typical European expression in the writings of the German Eduard Bernstein, but in Europe social democracy is practically the equivalent of socialism.

There are many varieties of socialism but all advocate some measure of governmental ownership and operation of the means of economic production. Some socialists favour only the nationalization of "key industries" while others advocate more extensive ownership not only of the means of production but of the means of distribution as well. The first significant socialist thought appeared in France in the 18th century—notably in the writings of François Noel Babeuf, the comte de Saint-Simon and Charles Fourier. Rejecting Adam Smith's belief that in following their own self-interests men are led by the "invisible hand" of Providence to promote the welfare of all, the socialists argued that the welfare of all could only be promoted by gradually abolishing the private ownership of the means of production and by deliberately reorganizing society in the interest of the workers.

Socialists propose to achieve their objectives by peaceful, democratic means (by persuasion and legislation) and generally favour the perpetuation of liberal democratic political institutions such as civil liberties, representative parliaments and the rule of law. Socialist measures have been adopted in Norway, Sweden, Denmark, the Netherlands, Belgium, Australia, New Zealand and Great Britain, among others.

Communism aims at achieving a world-wide socialist society through revolution and the "dictatorship of the proletariat." It rejects in practice, if not always in words, the principles of liberal democracy and finds theoretical support for its tactics in the dialectical materialism of Karl Marx as modified by the interpretation of the Russian Lenin. Expounding a brand of socialism which he described as "scientific," Marx argued that the victory of socialism over capitalism was preordained by the "laws" of history and of economics and that such a victory would be the inevitable result of a cataclysmic revolution to be undertaken by the proletariat or industrial working class. The "liquidation" of the capitalists and the transformation of society into a "classless society" was to be accomplished through a "dictatorship of the proletariat." Lenin held that this "dictatorship of the proletariat" could be nothing other than the dictatorship of the Communist party.

Whereas in communism the individual's interests are identified with those of the proletariat as those interests are interpreted by leading members of the Communist party, in fascism the individual must subordinate his own interests to those of the nation or "race" as those interests are interpreted by a single party claiming to speak for them. Fascism first appeared in Italy in 1922 under the dictatorship of Benito Mussolini and appeared in Germany in more ruthless form in 1933 under the dictatorship of Adolf Hitler. A fascist dictatorship was instituted in Argentina in 1943 under the leadership of Juan Perón. Both communist and fascist systems are characterized by a denial of the basic equality and dignity of human beings, by fanatical suppression of all opposition, by attempts to control politically every aspect of human life and thought and by a leadership principle which claims that a single leader or party infallibly represents the interests of the working class, nation or "race."

Messner, *Social Ethics* (1949); J. A. Schumpeter, *Capitalism, Socialism, and Democracy*, 3rd ed. (1950). (J. H. HL.)

**COLLEGE.** In Roman law a *collegium* was a body of persons, not fewer than three, associated together by the possession of common function. The nearest modern parallel is the corporation.

During the middle ages *collegia* might exist for trade purposes (as the English guilds); for political purposes (as the electoral college of princes which chose the king in medieval Germany); for ecclesiastical purposes, for example, collegiate churches; and, closely linked with the last, for educational purposes. In modern times the term is used occasionally for the Sacred college or College of Cardinals and for electoral colleges; but it most commonly denotes educational establishments, particularly those providing education beyond the level of compulsory schooling.

The name is not applied to schools for children within the public systems of education (though occasionally it is retained for historical reasons), but many independent schools in Britain carry it, a few, such as Winchester and Eton, because they were founded as *collegia*, but most because at the time of their foundation (usually in the 19th century) the name was held to connote social prestige or to indicate that the establishment provided secondary education—then largely a social privilege.

University colleges, a feature of Great Britain and the commonwealth, grew out of the practice of communal lodging in the middle ages. In Paris, in Oxford and in Cambridge scholars found it more satisfactory and safer to rent a house in which to live jointly than to live in isolated apartments. In these "houses of scholars," which were sometimes the gifts of benefactors or monastic foundations, one member was usually elected as magister, to speak and to be responsible for the rest. The transition from these endowed or unendowed hospitia, or hostels, to colleges with a legally recognized corporate entity was gradually made in the 13th century. The first absolutely clear instance in England was the foundation in 1264 of the "House of Scholars of Merton" (Merton college, Oxford) by Walter de Merton, chancellor of England and bishop of Rochester, though previous endowments laid the foundations of University and Balliol colleges at Oxford. Merton's statutes (made more explicit in 1270), which aimed at regulating the corporate life of the college, were closely followed in the foundation of Peterhouse, Cambridge, in 1284 and in later foundations. They enabled colleges to develop independently of the universities, and though later colleges and universities became virtually coextensive, this independence has been continuously preserved.

There are also in Britain theological colleges, teacher-training colleges, technical colleges, commercial and agricultural colleges, and so on. Apart from its educational use, the name is also borne by a few professional institutions, notably the Royal College of Physicians and of Surgeons, by the College of Arms (or Heralds' college; *i.e.*, the official repository of British family pedigrees) and by the College of Chaplains in the queen's household.

(H. C. D.)

In the United States the term college most commonly refers to a four-year undergraduate institution of higher education which admits students from secondary schools and which grants the bachelor's degree; it developed from the British universities, but has no exact counterpart in other countries. It usually emphasizes a liberal or general education rather than specialized technical or vocational preparation. It may be an independent privately controlled liberal arts college, or it may be the undergraduate division of a private or state university.

In American higher education the term college also refers to: (1) separate degree granting professional institutions, *e.g.*, state teachers colleges and medical colleges; (2) the constituent professional faculties of universities, *e.g.*, colleges of medicine, law, engineering, education, agriculture and commerce; (3) two-year nondegree-granting institutions known as junior colleges or community colleges; and (4) student residence halls in a few universities. The term is sometimes loosely applied to private business "colleges" offering training in routine office procedures and secretarial duties, the period of instruction ranging from a few weeks to two years.

See also UNIVERSITY; EDUCATION, HISTORY OF. For the U.S. electoral college, see UNITED STATES (OF AMERICA): Government. For the Sacred College of Cardinals, see CARDINAL. See also references under "College" in the Index.

(R. F. Bs.)

**COLLÈGE (FRANCE)**, a term used to denote several types

of secondary schools in the French educational system. See SECONDARY EDUCATION; EDUCATION, HISTORY OF.

**COLLEMBOLA**, an order of primitive, wingless insects commonly called springtails for their ability to catapult themselves into the air by use of an appendage attached to the underside of the abdomen. See SPRINGTAIL.

**COLLETT, (JACOBINE) CAMILLA** (née WERGE-LAND) (1813-1895), Norwegian author who first championed the rights of women in Norway. She was born at Christiania (Oslo), Jan. 23, 1813, and died there, March 6, 1895. She was influenced by her love for the poet J. S. Welhaven, her brother Henrik's opponent. Welhaven broke off the relationship and in 1841 Camilla married P. J. Collett, under whose guidance she began her literary career. Her life was darkened by the loss within six years of her parents, brother and husband, and her genius matured in loneliness. Her first novel, *Amtmandens dötter* (1854-55), was a fervent plea for woman's rights. The first realistic Norwegian novel, it inspired Henrik Ibsen, Jonas Lie and later writers. Social and emotional emancipation for women is championed also in *Sidste blade* (1868-73), *Fra de stummes leir* (1877) and *Mod strømmen* (1879-85). Camilla Collett's autobiographical sketches, *I de lange Nætter* (1863), reveal her sensitive and idealistic personality.

Camilla Collett's *Samlede Værker* were published in 3 vol. (1912-13). See also A. Benterud, *Camilla Collett. En Skjebne og et livsverk* (1947); E. Steen, *Diktning og virkelighet, en studie i Camilla Collett forfatter-skap* (1947).

(G. Rv.)

**COLLIER, ARTHUR** (1680-1732), English philosopher, who has had his admirers both in England and on the continent of Europe, was born at the rectory of Langford Magna, Wilts., on Oct. 12, 1680. Educated at Pembroke and Balliol colleges, Oxford, he became rector of Langford Magna in 1704. A close student of Descartes, of Nicolas Malebranche and of John Norris (*q.v.*), he shows no knowledge of Locke's work, but probably read Berkeley at a late stage in the development of his own ideas.

In his *Clavis Universalis* (1713) he denies, like Berkeley, that there is an external world, independent of mind. The fact that what we see seems to be external, he argues, is no proof that it actually is external; for we often experience apparently external objects (*e.g.*, in hallucinations or in double vision) which we nonetheless admit not to be external. Indeed, any imagined object seems to be external. The difference between a seen and an imagined object is not that the seen object possesses a quality of externality which the imagined object lacks, but that the seen is more vividly experienced than the imagined; and this does nothing to prove that it exists independently of us.

Furthermore, the very notion of an external world is self-contradictory. Philosophers, Collier anticipates Kant in arguing, have unanswerably demonstrated both that the external world must be finite and that it must be infinite; that it must, but cannot, be infinitely divisible; that it must, but cannot, contain motion. The only way out of these antinomies is to recognize that there is no external world; *i.e.*, that what we perceive exists only in relation to a mind. Only on this view, too, can we satisfactorily describe mind's relation to its objects and God's relation to created beings. Collier's metaphysics is outlined in his "Confession" (written in 1709) and theologically interpreted in *A Specimen of True Philosophy* (1730) and *Logology* (1732). There is, he says, one supreme substance, God, in relation to which everything else has only a dependent existence. (He was suspected of Arianism.) But within that substance there is an order of dependence which is also an order of perfection. In particular, the visible world of matter is dependent upon, and is less perfect than, the mind which perceives it. Collier has never exerted any considerable influence.

**BIBLIOGRAPHY.**—For *Clavis Universalis* see E. Bowman's edition (1909); or S. Parr, *Metaphysical Tracts by English Philosophers of the Eighteenth Century* (1837), which includes *A Specimen* and a brief précis of *Logology*. For the "Confession" see R. Benson, *Memoirs of the Life and Writings of Arthur Collier* (1837). See also J. H. Muirhead, *The Platonic Tradition in Anglo-Saxon Philosophy* (1931); and G. Lyon, *L'Idéalisme en Angleterre* (1888). On Collier and Berkeley, see G. A. Johnston, *The Development of Berkeley's Philosophy*, appendix i (1923). For Collier and Kant see A. O. Lovejoy, "Kant and

the English Platonists," in *Essays in Honour of William James* (1908); and H. J. de Vleeschauwer, "Les Antinomies kantiennees et la Clavis Universalis d'Arthur Collier," in *Mind* (1938). (J. N. A. P.)

**COLLIER, JEREMY** (1650–1726), English bishop of the Nonjurors (*q.v.*) and author of a celebrated attack on the immorality of the stage, was born at Stow-by-Quay, Cambridgeshire, Sept. 23, 1650. From Ipswich free school, where his father was Master, he entered Caius college, Cambridge in 1669. Ordained priest in 1677, he became chaplain to the countess dowager of Dorset and in 1679 rector of Ampton, near Bury St. Edmunds. He was made lecturer of Gray's Inn in 1685, but resigned at the Revolution and was sent to Newgate for writing *The Desertion Discuss'd* (1688), a pamphlet supporting James II and answering Bishop Burnet's *Enquiry Into the Present State of Affairs*. Released without trial after several months, he was again imprisoned in Nov. 1692 on suspicion of treasonable correspondence with James. He refused to acknowledge the court's jurisdiction by accepting bail, but was freed within ten days. In 1696 he daringly gave absolution on the scaffold to Sir John Friend and Sir William Parkyns, condemned for attempting to assassinate William III. His confederates in this act were imprisoned, but Collier absconded and lived under sentence of outlawry. When the storm subsided he returned to London. His first volume of *Essays*, an enlarged edition of the *Miscellanies* (1694, 1695), appeared in 1697. Further volumes followed in 1705 and 1709.

In his notorious *A Short View of the Immorality and Profaneness of the English Stage* (1698), Collier attacks Wycherley, Dryden, Congreve, Vanbrugh and D'Urfey, censuring them for indecency, for profane language, for abusing the clergy and for undermining public morality by sympathetic presentation of vice. He refers, in evidence, to the comparative decency of ancient drama, of Ben Jonson, of Corneille and, oddly, of Beaumont and Fletcher. Such critical principles as he employs are borrowed chiefly from René Rapin and Thomas Rymer (*q.v.*). Collier's eager accumulation of indecent examples combines unpleasantly with an ostensible moral indignation, and provided an easy target for his adversaries. In the ensuing pamphlet war, which lasted spasmodically until 1726, Congreve, Vanbrugh and D'Urfey, with Charles Gildon, John Dennis, Edward Filmer and James Drake, ranged themselves against Collier, Arthur Bedford, William Law, Whitelocke Bulstrode, Josiah Woodward and J. Field. Collier contributed the *Defence* (1699), the *Second Defence* (1700), the *Dissuasive* (1703) and the *Farther Vindication* (1708), and probably several later anonymous tracts, perhaps terminating with *The Conduct of the Stage Consider'd* (1721), which has been attributed to him.

Collier's *The Great Historical, Geographical, Genealogical, and Poetical Dictionary*, a translation, with additions, of Louis Moréri's *Grand Dictionnaire historique* (1674), was published in 1701, with supplementary volumes in 1705 and 1721. His *Ecclesiastical History*, 2 vol. (1708, 1714), was attacked by Bishops Kennett, Nicolson and Burnet on grounds of popery. Collier ably defended himself in *An Answer to Some Exceptions* (1715) and *Some Considerations on Dr. Kennet's . . . Letters* (1717). Consecrated in 1713 by George Hickes, the sole survivor of the nonjuring bishops, he was created, on July 23, 1716, primus of the church of the Nonjurors. He was a principal mover in the scheme, projected in 1716, for union with the Eastern Church and corresponded with the Orthodox authorities until 1725.

Collier favoured the 1549 Book of Common Prayer and regretted that later editions omitted certain usages from the communion service. His *Reasons for Restoring Some Prayers* (1717) recommended the reintroduction of the oblatory prayer, the invocation, the mixed chalice and the petition for the faithful departed. The consequent "usages" controversy split the nonjuring community and the ultimate extinction of the party may be attributed to this division. In 1718 was published a new *Communion Office* which embodied the changes required by Collier and was probably chiefly compiled by him. The exact dates of Collier's two marriages and the identity of his first wife are unknown. His marriage to Mrs. Cecilia Deacon, a widow, probably took place in 1716. Thomas Deacon, her son, was prominent among the nonjurors and possibly his extreme views influenced Collier in the "usages" con-

troversy. Collier's *Practical Discourses* (1725) were followed, the next year, by an appendix, *God Not the Author of Evil*. He died in London, April 26, 1726.

**BIBLIOGRAPHY.**—The biography in A. Kippis' *Biographia Britannica*, vol. iv (1789), was written partly by Collier himself. There is an informative *Life* in vol. ix of T. Lathbury's 9-vol. ed. of Collier's *Ecclesiastical History* (1852). For Collier's career as a nonjuring bishop see Lathbury's *A History of the Nonjurors* (1845). Sister Rose Anthony's *The Jeremy Collier Stage Controversy, 1698–1726* (1937) examines the *Short View* and its consequences. (Jo. C.)

**COLLIER, JOHN PAYNE** (1789–1883), English Shakespearean scholar and critic, whose great contributions to scholarship were marred by forgeries, was born in London on Jan. 11, 1789, the son of a journalist. He worked as parliamentary and law reporter, critic and editorial writer for the *Times* and *Morning Chronicle*, and, having entered the Middle Temple in 1811, was called to the bar in 1829. His interest in early English literature was stimulated by work on the *Critical Review*, and he produced a new edition of Robert Dodsley's *Old Plays* (1825–27), to which five more plays were added in 1833. Meanwhile he began to mix fraud with his genuine researches, first in his *History of English Dramatic Poetry and Annals of the Stage* (1831). His so-called "new facts and particulars" (1835–39), *Memoirs of E. Alleyn* (1841), *Alleyn Papers* (1843) and the *Diary of P. Henslowe* (1845) combine close scholarly work on neglected and important texts with imposture. Collier added to Henslowe's diary, for instance, and claimed to incorporate in his eight-volume annotated Shakespeare (1842–44) manuscript corrections from a copy of the First Folio. This was supplemented by useful work on *Shakespeare's Library* (1843) and *Book Entries of the Stationers' Register* (1848–49), but during 1852 he announced in letters to the *Athenaeum* the discovery of a copy of the Second Folio, with mid-17th-century annotations (the so-called Perkins Folio, from the name on the title pages). In the notes, punctuation and stage directions were changed; there were cancellations, numerous emendations and additions to the text of up to nine lines. These "revisions" were incorporated into *Notes and Emendations to the Text of Shakespeare's Plays* (1852) and a one-volume edition of Shakespeare (1853). The authenticity of the additions and substitutions was questioned by Alexander Dyce, Charles Knight, Howard Staunton and James Halliwell, and the first doubts were published by S. W. Singer in *The Text of Shakespeare Vindicated* (1853) and by E. A. Brae, anonymously, in *Literary Cookery* (1855). Brae attacked again five years later in *Collier, Coleridge and Shakespeare*, as Collier had by then allegedly discovered his long-lost notes to Coleridge's lectures on Shakespeare. However, Collier's faith in the Perkins Folio was sustained in the 1858 edition of Shakespeare, and it had meanwhile been presented to the duke of Devonshire and subsequently to the British museum for examination (1859). The fabrications were reported in the *Times* by N. E. Hamilton, who also made inquiries into Collier's other papers. The press took up the controversy, but expert opinion was against Collier. Only after his death at Maidenhead, Surrey, on Sept. 17, 1883, was it confirmed, however, that Collier was the actual forger and not merely a dupe. This notoriety inevitably undermined confidence in all Collier's work, even where it was intelligent, useful and honest. His services to the Percy and Shakespeare societies, for instance, should be mentioned; so should his editions of Thomas Heywood (1842–51) and Spenser (1862), and his *Bibliographical and Critical Account of the Rarest Books in the English Language* (1865). And even where he misused documents (as in the Henslowe papers) he directed to them an overdue attention.

See H. B. Wheatley, *Notes on the Life of John Payne Collier, With a Complete List of His Works* (1884); C. M. Ingleby, *A Complete View of the Shakespeare Controversy* (1861). (G. A. O.)

**COLLIMATOR**, a lens (*q.v.*) placed at a distance equal to its focal length from the luminous object under examination; the rays proceeding from the lens are thus rendered parallel, which is equivalent to the removal of the luminous object under examination to an infinite distance, without the loss of light intensity which such removal entails.

Specialized measurements in geometrical and physical optics and

spectroscopy require this collimation of the light. In these cases the collimator is usually a telescope with a slit at the principal focal length of the lens. Light from the luminous source is focused on this slit by a lens of similar focal length and the slit then serves as the luminous object of the optical system.

See also OPTICS.

**COLLIN, HEINRICH JOSEF VON** (1771-1811), Austrian dramatist and poet whose plays reflect the change from classicism to romanticism, was born in Vienna, Dec. 26, 1771, and died there, July 28, 1811. He wrote patriotic lyrics against Napoleon (*Wehrmannslieder*, 1809) and ballads on medieval subjects (*Gedichte*, 1812). His early plays were in the strict form of French classicism, but later he was influenced by German romanticism. His plays include *Regulus* (1802), *Polyxena* (1803) and *Coriolan* (1804), to which Beethoven wrote an overture.

Collin's *Gesammelte Werke* appeared in 6 vol. (1812-14). See also F. Laban, *H. J. von Collin* (1879); M. Lederer, *H. J. von Collin und sein Kreis* (1921). (H. F. GN.)

**COLLINGS, JESSE** (1831-1920), British politician and agrarian reformer, a strong advocate of the "three acres and a cow" radical land reform policy. He was born at Littleham-cum-Exmouth, Devon, on Jan. 9, 1831. His first employment was as a junior clerk with a mercantile firm, over which he took direction in 1864. He was interested in social questions before he moved to Birmingham in the 1860s and soon became prominent in local radical politics. In 1867 he was appointed secretary of the Birmingham Education society and two years later of the influential National Education league, which developed from it. He had become a member of the Birmingham town council in 1868, and was soon prominent as one of Joseph Chamberlain's (q.v.) closest associates, succeeding him as mayor in 1878. In 1880 he entered parliament as Liberal member for Ipswich, and from this agricultural constituency urged an "unauthorized program" of land policy, originally canvassed in 1872 when he helped to found the Rural Labourers' league, associated with the slogan "three acres and a cow." In Jan. 1886 he moved the small-holdings amendment to the address which caused the resignation of Lord Salisbury's government, and became parliamentary secretary to the Local Government board in the new ministry of W. E. Gladstone. In March he resigned with Chamberlain in opposition to Gladstone's Home Rule policy. At the general election in July he lost his seat at Ipswich on petition, but soon after was returned for Bordesley, Birmingham. Although he tried to maintain his radical land ideas, Liberal opposition to him led to his removal from the presidency of the Allotment and Small Holdings association in 1888, and, closely following Chamberlain, he moved increasingly away from radicalism toward the Conservative party. In 1895 he became undersecretary to the home office in Salisbury's government, retaining the post until 1902. He resigned from parliament in 1918 and died at Edgbaston, Birmingham, on Nov. 20, 1920. His chief works are: *Land Reform* (1906); *The Colonization of Rural Britain*, 2 vol. (1914); and *The Great War* (1916). An autobiography was published by J. L. Green (1920). (A. BRI.)

**COLLINGWOOD, CUTHBERT COLLINGWOOD**, BARON (1748-1810), British naval commander who was Nelson's second-in-command at Trafalgar and held the Mediterranean command thereafter, was born at Newcastle upon Tyne on Oct. 24, 1748, and was sent to sea at the age of 12 in the frigate "Shannon" in the care of his cousin, Captain Braithwaite. He served for several years on the home station with that officer and also under Adm. Robert Roddam. In 1774 he served on the North American station under Adm. Samuel Graves and was in the naval brigade that saw service at the battle of Bunker Hill, there winning his lieutenantcy (June 17, 1775). In the following year he was lieutenant of the sloop "Hornet" in the West Indies, and thereafter began his close association with Horatio Nelson. He followed Nelson as commander of the "Badger" and captain of the frigate "Hinchinbrooke" (March 1780). After commanding another frigate and the "Sampson" of 64 guns, Collingwood found himself again with Nelson in the West Indies, this time in the frigate "Mediator." He remained there three years and was present during the difference between Nelson and the commander in chief concerning the se-

verity with which the Navigation laws ought to be enforced against the United States. He agreed with Nelson, with whom he was by now on intimate terms, that no leniency should be shown.

In 1786 Collingwood returned home and, with the exception of one brief command, remained there until 1792. On the outbreak of the French Revolutionary Wars, he was appointed flag captain to Rear Adm. Sir George Bowyer in the "Prince," and with him he shifted to the "Barfleur" and took part in Lord Howe's victory on the "glorious first of June," 1794. In Aug. 1795 he was appointed to the "Excellent" for his first experience of the Mediterranean station; he was engaged in the blockade of Toulon and took a conspicuous part in Sir John Jervis' victory off St. Vincent (Feb. 1797). When Jervis divided the Spanish line, the "Excellent" was the rearmost ship in his fleet and when Nelson, anticipating orders, turned his ship out of the British line to oppose Spaniards that seemed likely to escape, it was to Collingwood that Jervis signaled to go to his friend's assistance. He was already on his way. He and Nelson found themselves greatly outnumbered, until other ships arrived, but the Spanish flight was held up and four ships were made prize. In 1799 Collingwood became rear admiral, and he was at sea in the "Triumph" and other ships until the peace of Amiens in 1802.

On the renewal of war in 1803, Collingwood was at once employed. He began in the channel fleet, under Sir William Cornwallis, which was blockading Brest. He remained there until May 1805 (having in the meantime been promoted to vice-admiral in May 1804), when he was given command of a small squadron which was intended to reinforce the Mediterranean fleet under Nelson. He placed himself off Cádiz when Adm. P. C. de Ville-neuve, after his return from the West Indies, made that port, and there he was joined by Nelson, so becoming second-in-command at Trafalgar. In this battle he carried out brilliantly the part assigned to him by the commander in chief. With 15 ships he was to attack the rear of the enemy to prevent their escape. As his flagship "Royal Sovereign" was newly from the dockyard, and a fast sailer, he was the first to engage the enemy and had almost forced a Spanish flagship to strike to him before any other British ship had fired a gun. On Nelson's death in the battle, command passed to Collingwood, and he had the difficult task of conserving the fleet and its prizes during the storm which followed. For his services he was created Baron Collingwood and granted a pension of £2,000 a year.

The completeness of victory at Trafalgar prevented Nelson's immediate successors from achieving any comparable triumph, but Collingwood held the Mediterranean command with distinction until his death. He had wished to retire, but the admiralty would not spare him. As well as being a distinguished leader, he was a gunnery expert, a man of great political insight and diplomatic ability, benevolent and generous both as a commander and as a private person and an excellent letter writer. He died at sea, March 7, 1810, and was buried near Nelson in St. Paul's cathedral.

**COLLINGWOOD, ROBIN GEORGE** (1889-1943), English philosopher and historian, born at Coniston in Lancashire, early acquired artistic and scholarly tastes from his father, the friend and biographer of John Ruskin. He was educated at Rugby and at Oxford (University college), where he came under the influence of F. J. Haverfield and so was drawn into those archaeological and historical studies which were to make him the leading authority in his day on Roman Britain and culminated in his *Roman Britain* (1936), a volume of the *Oxford History of England*. These studies, however, were secondary to his profession as a philosopher. He became a fellow of Pembroke college, Oxford, in 1912 and taught philosophy there until he went to Magdalen college as Waynflete professor of metaphysical philosophy. This chair he held from 1935 to 1941, when he resigned because of ill health. He finally returned to Coniston and died there Jan. 11, 1943. Collingwood regarded it as his life work to bring about a *rapprochement* between philosophy and history. Philosophers

since Descartes, he thought, had been too much preoccupied with science and so with methods and concepts inapplicable in the study of thought or action. Two world wars had convinced him that the sciences had been unable to solve the problems of human affairs, but a philosophy fused with history seemed to him to promise more success. The last of his works, *The New Leviathan* (1942), contains his only contribution to this result, but he had earlier made history the *Leitmotiv* of his work by arguing that the task of metaphysics was the historical one of disentangling and expounding the fundamental beliefs presupposed by a given civilization, or by natural science, or by history at different periods in their evolution. All his life he was keenly interested in art, and he both painted and composed. This first-hand experience gives a special freshness to his remarkable work on aesthetics, *The Principles of Art* (1938). His most important work, however, is perhaps his *Essay on Philosophical Method* (1933), where in defiance of logical analysis, the type of philosophy dominant in his day, he goes back to Plato and Georg Hegel and argues that the way to understand any philosophical concept (e.g., goodness) is to recognize it as a universal whose varying particularizations (e.g., pleasure, utility and duty) are specified on a scale of which each stage differs both in degree and in kind from its predecessor.

(T. M. K.)

**COLLINGWOOD**, an inner suburb of Melbourne, Victoria, Austr., lying on the Yarra river about 2½ mi. N.E. of the centre of the city. Pop. (1954) 27,155. Named after Adm. Cuthbert Collingwood, the town has grown into a thickly populated and highly industrialized quarter of Melbourne, its chief industries being the manufacture of footwear and textiles. It has two large technical schools and extensive parklands, arenas and sports grounds.

(G. J. BN.)

**COLLINS, ANTHONY** (1676–1729), English deist and free-thinker, was born at Heston, near Hounslow in Middlesex, on June 21, 1676. He was educated at Eton and King's college, Cambridge. An important influence in his life was his intimacy with John Locke, who in his letters speaks highly of him. Collins died at his house in Harley street, London, on Dec. 13, 1729.

His writings summarize the work of previous English free-thinkers. Though unorthodox, Collins was not an atheist, nor even an agnostic. In his own words, "Ignorance is the foundation of atheism and freethinking the cure of it" (*A Discourse of Free-Thinking*, p. 105).

His first work of note was *An Essay Concerning the Use of Reason in Propositions the Evidence Whereof Depends on Human Testimony* (1707), in which he rejected the distinction between *above* reason and *contrary* to reason and demanded that revelation should conform to man's natural ideas of God. Like all his works, it was published anonymously. In 1713 appeared his chief work, *A Discourse of Free-Thinking, Occasioned by the Rise and Growth of a Sect Called Free-Thinkers*. In England this essay, taken as a plea for deism, caused a sensation, calling forth numerous replies.

In 1724 Collins published *A Discourse of the Grounds and Reasons of the Christian Religion*, with *An Apology for Free Debate and Liberty of Writing* prefixed. Ostensibly, it is written in opposition to William Whiston's attempt to show that the books of the Old Testament did originally contain prophecies of events in the New Testament which had been eliminated or corrupted by the Jews, and to prove that the fulfilment of prophecy by the events of Christ's life is all "secondary, secret, allegorical and mystical." No less than 35 answers were directed against this book, the most noteworthy being those of Bishop Edward Chandler, Arthur Sykes and Samuel Clarke. Collins replied with the *Scheme of Literal Prophecy Considered* (1727). An appendix holds, against Whiston, that the book of Daniel was forged in the time of Antiochus Epiphanes.

In philosophy, Collins is a defender of necessitarianism. His brief *Inquiry Concerning Human Liberty and Necessity* (1715) is an excellent outline of the determinist position. Attacked by Samuel Clarke, he replied after Clarke's death with a dissertation on *Liberty and Necessity* (1729).

Collins also wrote *A Letter to Mr. Dodwell* (1707), arguing that it is conceivable that the soul may be material and, secondly, that

if the soul be immaterial it does not follow, as Clarke had contended, that it is immortal; *Vindication of the Divine Attributes* (1710); and *Priestcraft in Perfection* (1709).

**COLLINS, JOSEPH LAWTON** (1896– ), U.S. army officer, commander of the VII corps in Europe during World War II, was born in New Orleans, La., May 1, 1896. On graduation from the United States Military academy at West Point in 1917, he was commissioned second lieutenant of infantry. He served with occupation forces in Germany, 1919–21.

In 1941 Collins was chief of staff, VII corps, and then chief of staff, Hawaiian department. He was commander of the 25th division in the Pacific, 1942–44, and of the VII corps in Europe, 1944–45. The latter force landed on Utah beach in Normandy on June 6, 1944, later captured Cherbourg, led the breakout from Normandy, pierced the Siegfried line, captured Aachen and Cologne, enveloped the Ruhr from the south and east, and then drove eastward to a meeting with the Russians on the Elbe at Dessau.

Collins, who attained the rank of general in 1948, served as chief of staff, U.S. army, 1949–53, and in 1953 became U.S. representative to the military committee and standing group of the North Atlantic Treaty organization. In 1954 he served as special representative of the United States in Vietnam. (F. C. PE.)

**COLLINS, MICHAEL** (1890–1922), Irish revolutionary leader and a hero of the struggle for independence, was born near Clonakilty, County Cork, on Oct. 16, 1890, the eighth child of Michael Collins, a prosperous farmer, and his young wife, Mary Anne O'Brien, whom he had married at the age of 62. He entered the British civil service and went to London in 1906. He stayed for ten years, working first as a postal clerk and then in a solicitor's office. During this time he became interested in Irish nationalist activities and in 1909 joined the Irish Republican brotherhood.

In 1916 Collins returned to Ireland in time to fight under P. H. Pearse in the Easter rising at Dublin. He escaped being taken under arms but later was arrested and sent with the great body of suspects to the detention camp at Frongoch, Wales. Released with the rest in Dec. 1916, he was returned at the general election in Dec. 1918 as Sinn Féin member for West Cork. Out of 73 elected only 27 were present when the *dail eireann* (assembly of Ireland) met in the Mansion house and declared for the Irish republic. Eamon de Valera, their elected president, was in jail, so was the vice-president, Arthur Griffith. Much responsibility now fell on Collins, who became first Sinn Féin minister for home affairs and, after the dramatic escape of De Valera from Lincoln jail in Feb. 1919 (for which Collins was largely responsible), minister for finance. But it was in his military capacity as adjutant general of the volunteers and director of organization and of intelligence for the Irish Republican army that Collins became famous. Until 1921 and during the time when he was head of the list of men "wanted" by the British authorities, Collins discharged the responsibilities of these various offices. He controlled the entire correspondence of the revolutionary movement and almost all enterprises were considered, financed and many were also carried out by him. A reward of £10,000 was offered for his arrest and pictures of him were published. Yet he used no disguise, went about Dublin alone on a bicycle and frequently made appointments for an interview in the streets. He helped to demoralize the British secret service and created a most effective spy system of his own. In the debate on the Irish treaty in the *dail* Griffith was to speak of Collins as the man "who won the war."

When the truce with Britain was proclaimed in July 1921, Collins for the first time became directly known to the Irish public. No other figure was so popular. Griffith and Collins were the principal Irish plenipotentiaries at the negotiations in London in Oct.–Dec. 1921. By his genial personality and his realism Collins undoubtedly smoothed over many of the difficulties. Though in principle a republican he was not a doctrinaire and signed the treaty on Dec. 6, 1921, as marking the greatest advance in Ireland's status that could be obtained in the circumstances. He recognized that

in so doing he was almost certainly signing his own death warrant. In the ensuing debate in the *dail*, Griffith alone could not have persuaded the majority to approve the treaty against De Valera's opposition. This achievement was largely due to the magnetic personality of Collins. When the result of the voting (Jan. 1922) showed the narrow majority of seven for acceptance, Collins warned the *dail* of the anarchy that might follow dissension.

The first result of the *dail's* decision was confusion. Griffith was elected president, not of the Free State but of the Irish republic. Collins was appointed chairman of the provisional government, but administration in the ordinary sense was impossible. Civil life had been destroyed in the guerrilla war; the Royal Irish constabulary was disbanded; the British garrison was evacuating the country, and the Irish army, still considered the army of the republic, was disaffected. Mutiny broke out and Collins, hoping against hope to avoid civil strife, refrained from drastic action. He was instrumental in postponing the general election (stipulated for under the treaty), and when at last a date for it was fixed in June he entered into a compact with De Valera by which he and the republican leader agreed to appeal for the unopposed return of candidates jointly nominated by them. This would have given a very large representation to opponents of the treaty. When, however, independent candidates were put forward, Collins at the last moment advised his countrymen to vote as they wished. At the elections the republicans were heavily beaten and the Irish government challenged by force even in the capital, decided to use force in return.

Civil war began. Collins, assuming chief command, flung himself into the struggle with all his energy. Opposition was crushed in Dublin and all the large towns. Suddenly, on Aug. 12, 1922, Griffith collapsed and died and Collins became at once head of the state and of the army. He went to Munster, where the chief resistance lay. On Aug. 22, traveling with a strong escort from Skibbereen to Cork, his party was ambushed at Beal-na-Blath, and in the skirmish he was shot through the head. No man since C. S. Parnell had so caught the imagination of Ireland. See also IRELAND, REPUBLIC OF: *History*.

**BIBLIOGRAPHY.**—P. Beasley (Beasley), *Michael Collins and the Making of a New Ireland*, 2 vol. (1926); Frank O'Connor, *The Big Fellow* (1937); Rex Taylor, *Michael Collins* (1958). (S. G.; P. N. S. M.)

**COLLINS, WILLIAM** (1721–1759), English poet in whose hands one of the most rigid poetic conventions of his time, the personified abstraction, became the vehicle for a unique vision of reality. He was born at Chichester on Dec. 25, 1721, the son of a wealthy hatter and mayor of that town.

Collins' literary career was brief and, in terms of bulk, not very productive; yet he was a precocious writer. He was sent to Winchester college, where he established one of the most stable and fruitful relationships of his unstable life, with his fellow poet Joseph Warton. Tradition speaks of a poem "On the Battle of the Schoolbooks," written in Winchester when he was 12. On the other hand a poem "On the Royal Nuptials," printed in 1734 but lost, which was long attributed to Collins, seems to have been the work of another. More certainly his are the verses, "When Phoebe Formed a Wanton Smile," in the *Gentleman's Magazine* for 1739, and the "Song. The Sentiments Borrowed From Shakespeare," both apparently composed while Collins was a schoolboy. He was only 17 when, under the influence of Pope's *Pastorals*, he composed his four *Persian Eclogues* (published in 1742; 2nd ed. as *Oriental Eclogues* in 1757) which alone of his works were much esteemed in his lifetime. Published when Collins was at Magdalen college, Oxford, they were followed the next year by his *Verses Humbly Address'd to Sir Thomas Hanmer*, in heroic couplets. To a second and revised edition, published as *Epistle: Addressed to Sir Thomas Hanmer*, issued the next year over the poet's name, was appended the exquisite "Dirge from Cymbeline." It is already notable how these early pieces lean upon other poems; what is more striking, in view of their date, is that the precedent they lean on most is Shakespeare.

Collins graduated in 1743 and, having failed to secure a fellowship, came to London in 1744. By the death of his mother in this year he came into a little money, and with further allowances

from his uncle, Colonel Martin, who had supported him at Oxford, he was able to live for the time as a man about town. He made friends with both Garrick and Johnson; the latter expressed respect for his talents and, later, concern for his fate. By 1746 Collins was in and out of the bailiff's hands, and there was mention of a project (one of many which came to nothing) to translate Aristotle's *Poetics*. Meanwhile he had agreed to collaborate with Warton on a volume of odes. In the outcome Warton's odes and Collins' appeared separately, both in Dec. 1746, the title page of Collins' *Odes* being dated 1747. Warton's collection was well received, but Collins' *Odes on Several Descriptive and Allegorical Subjects* (the title was exact and considered) was barely noticed. Collins, though indignant, continued to practise the style announced and exemplified in the "Ode to Simplicity" and he surpassed himself in the "Ode to Evening" and "Ode Written in the Beginning of the Year 1746," both published in Dodsley's *Miscellany*, and in an elegiac ode on James Thomson, with whom Collins had been intimate in the last years before Thomson's death in 1748. In 1746 Dodsley's *Museum*, to which Collins may also have contributed some essays, printed "A Song. Imitated from the Midsummer Night's Dream of Shakespeare," a poem now attributed to him.

In April 1749 Colonel Martin died, leaving his nephew enough money to extricate him from his debts. In the next few months Collins wrote a lost poem, "Epistle to the Editor of Fairfax His Translation of Tasso," and also his "Ode on the Popular Superstitions of the Highlands of Scotland." This, left unperfected, was addressed to John Home, author of *Douglas*; it anticipates most strikingly some attitudes and interests of the romantic revival. In 1750, in a letter to William Hayes, who had set to music the ode on "The Passions" for public performance in Oxford, Collins wrote of another ode, now lost, on "The Music of the Grecian Theatre." In 1754, after a vain attempt to cure himself by travel of the mental illness, joined with physical debility, which had threatened him since 1751, Collins was confined in a lunatic asylum. Released to the care of his sister, he survived wretchedly in Chichester until June 12, 1759.

Although some theorists had allowed that personification could play a more positive role in poetry than merely to permit of economical phrasing, although in contemporary painting and funerary sculpture personifications were sometimes profoundly imaginative and although the Wartons had elevated this possibility into a conscious poetic program, only Collins constantly visualized his personifications so intensely as to transform them from set pieces of allegory into visionary apprehensions of a transcendent world. Enthralled by this possibility and dedicated to achieving it, Collins vowed himself to a classicism more thoroughgoing and exacting than his contemporaries conceived of. In particular it was Greek rather than Roman and it turned upon what Collins exalted as "simplicity." This has nothing to do with plainness and easiness (his diction for instance is throughout choice, sumptuous and elaborate), but rather has the meaning of "severity." It shows itself particularly in a calculated avoidance of sensuous appeal, as (consummately) in the "Ode to Evening," where the abstraction, Evening, is made concrete by steady negation of all sounds but the faintest, all colours but the most subdued. The severity that everywhere precluded rhythms in the least insistent or intoxicating here precluded rhyme also. Yet in fact, and by this very process of negation, the world evoked by Collins is very distinctly present to the senses, as a world above all damp and chill. The noble elegy on Thomson is only one example of how Collins assigns moral values to moistness and cold, sensations which he consistently associates with spiritual worth and achievement.

Chapin, *Personification in Eighteenth-Century English Poetry* (1955). There is a bibliography in I. A. Williams, *Seven 18th Century Bibliographies* (1924).

(D. A. DE.)

**COLLINS, WILLIAM WILKIE** (1824–1889), English novelist, and an early master of the mystery story, was the elder son of William Collins (1788–1847), the landscape painter. He was born in London on Jan. 8, 1824, and died there on Sept. 23,

1889. At the age of 12 he was removed from the Maida Hill academy to accompany his parents to Italy; returning two years later, he was sent to a private boarding school in Highbury, where the senior boy is said to have employed him as a storyteller, rewarding success with pastries and visiting failure with a cat-o'-nine-tails. He was articled to a firm in the tea trade, but soon abandoned commerce to enter Lincoln's Inn. Although called to the bar in 1849 he had no disposition to practise law. He worked on a historical novel, had a picture hung at the Royal academy, engaged in theatricals and visited Paris where he was attracted by the morgue. His father had died in 1847, and his first essay in literature was *The Life of William Collins*, published in 1848. Then his fiction began to appear: *Antonina, or The Fall of Rome* in 1850; *Basil*, a highly coloured tale of seduction and vengeance with a contemporary middle-class setting and passages of uncompromising realism, in 1852; *Hide and Seek, or The Mystery of Mary Grice* in 1854. He made the acquaintance of Dickens, to whose *Household Words* he contributed as serials *After Dark* (1856) and *The Dead Secret* (1857). His first major achievement, *The Woman in White* (1860), is based upon a French *cause célèbre*, but its opening has been declared to contain a reminiscence of Collins' first encounter with Caroline Courtenay, his mistress for many years. Among his most successful subsequent books were *No Name* (1862), *Armada* (1866) and *The Moonstone* (1868). The quality of his later writing shows a steady decline. His health was poor and he made injudicious use of opium.

Collins was one of the first and greatest masters of the mystery story, a literary kind which was to proliferate astonishingly in the 50 years after his death. Less concerned than Edgar Allan Poe to emphasize the intellectual aspect of detection, he lends to the progressive elucidation of unaccountable events and perplexing situations something of the traditional amplitude of the English novel. *The Moonstone* is a masterpiece of construction and *Armada* of controlled melodrama; Count Fosco in *The Woman in White* is the illustrious original of innumerable bravura villains.

See Kenneth Robinson, *Wilkie Collins* (1951). (J. I. M. S.)

**COLLITZ, HERMANN** (1855–1935), German-U.S. philologist, noted for his work on the Indo-European languages, particularly the Germanic languages, was born Feb. 4, 1855, at Bleckede near Lüneburg. He entered the University of Göttingen in 1875, where he studied under a number of distinguished scholars; he received his doctorate in 1878. His dissertation dealt with the origin of the Indo-Iranian palatal series of consonants. In collaboration with Bechtel and others he edited the *Sammlung der griechischen Dialektinschriften* (4 vol., Göttingen, 1884–1915). During the later period of his life, however, and especially after he settled in the U.S., his teaching and publications were devoted mainly to the comparative and historical study of the Germanic languages. After several years in Berlin and Halle, Collitz went in 1886 to Bryn Mawr college, Pa., as associate professor of German. In 1907 he became professor of Germanic philology at Johns Hopkins university in Baltimore, Md., where he remained as emeritus professor after 1927. In 1912 his book *Das schwache Präteritum* was published. He died on May 13, 1935. (J. W. P.)

**COLLODION**, a colourless, sticky fluid, made by dissolving guncotton and the other varieties of pyroxylin (see NITROCELLULOSE) in a mixture of alcohol and ether. It was first described in 1846 by the Swiss-German chemist C. F. Schönbein, discoverer of guncotton. The quality of collodion differs according to the proportions of alcohol and ether and the nature of the pyroxylin it contains. Collodion in which there is a great excess of ether gives by its evaporation a very tough film; the film left by collodion containing a large quantity of alcohol is soft and easily torn. Under the microscope, the film produced by collodion of good quality appears translucent and colourless. To preserve collodion it should be kept cool and out of the action of the light. For the iodizing of collodion, ammonium bromide and iodide and the iodides of calcium and cadmium are the agents employed. (See PHOTOGRAPHY.) Collodion is used in surgery since, when painted on the skin, it rapidly dries to a thin contractile film, affording both pressure and protection. Flexible collodion, con-

taining Canada balsam and castor oil, does not crack, but, on the other hand, does not contract.

**COLLOID**, a substance in a particularly fine state of subdivision, much larger than atomic or simple molecular dimensions, but much smaller than particles visible to the unaided eye. The art of preparing and processing colloidal materials goes back many thousands of years; as far back, in fact, as civilization itself. Colloids and colloidal materials are vital to everyday life, common examples being butter, cheese, dough, inks, paints, silk, wool and other fibres, soils, rubber, plastics, potter's clay, even fog and smoke, to mention only a few. The long-known method of splitting open rocks by inserting dry wooden wedges, which are then moistened, is an interesting practical use of the swelling pressures of colloids. The alchemists of the middle ages were familiar with "potable gold" (a gold suspension still used for medicinal purposes), and the preparation of gold ruby glass goes back to the 16th century.

  3. Gels
  4. Association Colloids (Soaps and Dyes)

## I. HISTORY

The scientific study of colloids dates only from the beginning of the 19th century, and of the early investigators special mention must be made of F. Reuss, Robert Brown, F. M. Ascherson and Francesco Selmi. Reuss (1809) packed a clay plug into a U tube, and after filling the two sides with water applied a potential from a voltaic cell across the plug. The small suspended particles of clay were seen to move toward the positive electrode, and after some time the water level stood lower in the arm containing this electrode. Such movements of suspended colloidal particles and of liquid under an applied electrical field are termed "electrophoresis" or "cataphoresis" and "electroosmosis" respectively.

If suspensions of very finely divided (colloidal) particles are examined under the microscope they are seen to undergo ceaseless irregular movements, termed the Brownian movement (*q.v.*) in honour of the botanist Robert Brown, who in 1827 first recorded the phenomenon with aqueous suspensions of pollen. Brownian motion is now known to be caused by the irregular bombardment of the molecules of the surrounding liquid, and its study provided one of the earliest and most striking pieces of evidence in support of the real existence of atoms and molecules and of the simple kinetic theory.

In 1838 Ascherson, then lecturer in medicine at the University of Berlin and interested in the physiological role of fats, gave a paper to the Paris Academy of Sciences upon his studies of olive-oil droplets in the presence of dissolved proteins (*e.g.*, egg white or serum). He records that "coagulation in form of a membrane occurs inevitably and instantaneously when albumin comes into contact with a liquid fat." This observation explained the skins around fat droplets in living systems and laid the basis for the study of "denaturation" of proteins at interfaces.

Francesco Selmi, an Italian professor, published (1845–50) the first systematic study of inorganic colloids, in particular silver chloride, prussian blue and sulfur. Selmi showed that salts would coagulate these colloidal bodies and that they differed in their precipitating power. From the absence of heat changes upon coagulation or upon peptization he concluded that the dispersed particles were not in a state of molecular dispersion, a conclusion fully vindicated by later work.

Thomas Graham (1805–69) is usually regarded as the founder of modern colloid science, although his contributions to other branches of chemistry were also outstanding. Of his 46 publications the two of particular interest here are entitled *Liquid Dif-*

*fusion Applied to Analysis* (1861), and *On the Properties of Silicic Acid and Other Analogous Colloidal Substances* (1864). Graham realized very clearly the properties that we regard as characterizing the colloidal state, such as low diffusivity, absence of crystallinity and of ordinary chemical relations, as well as its biological significance. Low diffusivity arises from the large size of colloidal particles ( $c. 10^{-7}$  cm. to  $c. 10^{-3}$  cm.) as compared with ordinary molecules.

The term "colloid" (from the Greek word for glue) was coined by Graham in 1861 and applied by him to substances such as gelatin, albumin, gums, etc., which are retained by membranes such as parchment paper when subjected to dialysis (*q.v.*). Substances such as salts, sugars, etc., which readily pass through the membrane, he termed "crystalloids," by virtue of the comparative ease with which they could be obtained in crystalline form from their solutions. Of Graham's other contributions to the nomenclature of colloids, those still in use are the terms "sol," "gel," "peptization" and "syneresis." A sol is a dispersion of a solid in discrete units, the type of dispersion medium being shown by a prefix; *e.g.*, hydrosol (for dispersions in water), aerosol (for dispersions in air), etc. If the solid particles were linked together to form a structure with some mechanical strength the system was termed a gel. Peptization—from analogy with peptic digestion—referred to the spontaneous dispersion of a precipitate to form a colloid, as for example, the dispersion of a precipitate of prussian blue when an attempt is made to wash it. Syneresis was the term suggested by the study of silicic acid (obtained from water glass and dilute acids) for the phenomenon of spontaneous shrinkage of a gel with exudation of the dispersion medium.

Gold sols, prepared by reducing dilute solutions of gold chloride, are usually strikingly coloured (ruby red, blue, green, etc.). Although they were known to the alchemists of the 17th century, it was Michael Faraday (1857) who first made a scientific study of their preparation and properties. He showed that addition of salts turned the ruby sols blue and then coagulated them, and that these effects could be prevented by addition of gelatin and other hydrophilic colloids. The ruby sols, which had all the appearances of solutions, were shown by him to contain particles (of gold) since, unlike true solutions, a cone of light passing through them became visible to an observer situated at right angles to the beam. This phenomenon was later studied in more detail by John Tyndall, and is usually referred to as the "Tyndall effect."

Of the metal sols, those of silver were much studied, particularly by Carey-Lea (1823-97) in the U.S., in connection with the photographic process. The preparation and purification of sols were facilitated by electrodialysis, and by ultrafiltration, *i.e.*, filtration through porcelain filters of very fine pore size.

The stability of hydrophobic sols to salts was quantitatively examined by Hans Schulze (1882) and somewhat later by W. B. Hardy. Electrophoresis had shown that all colloids carry a charge to which hydrophobic colloids owe their stability, since the like charges prevent collision. According to the Schulze-Hardy rule, coagulation is brought about by the ion carrying the opposite charge to that on the colloidal particle, and the coagulating power of an ion increases very rapidly with its charge (*e.g.*, to coagulate negatively charged sols such as Au or  $As_2S_3$ , the requisite concentration of  $Na^+$ ,  $Ca^{2+}$  and  $Al^{3+}$  are approximately in the ratio 1:170:1/900).

Addition of a hydrophilic colloid to a hydrophobic one protects it from the coagulating action of salts, a phenomenon termed protection and first pointed out by Faraday.

Hydrophilic colloids such as the proteins are only precipitated by high concentrations of salt. For a series of salts the efficacy runs approximately parallel to the solubility in water (F. Hofmeister, 1888), indicating that precipitation is caused by dehydration of the colloid. A series of cations or anions in order of coagulating power (*e.g.*,  $Li^+ > Na^+ > K^+$ ) is termed the Hofmeister or lyotropic series.

In 1903 a notable advance was introduced in the techniques for examining colloidal systems with the invention of the ultramicroscope by H. Siedentopf and R. Zsigmondy (*see* MICROSCOPE: *Ultramicroscope*). The chief difference from the usual method of

microscopic examination was the mounting of the microscope at right angles to the incident beam; the colloidal particles, because of the light they scatter laterally, then stand out as bright points of light on a dark ground. This apparatus can detect particles down to about 100 Å in size, compared with about 2000 Å ( $0.2 \mu$ ) for the ordinary microscope.

Jean Perrin in 1905 introduced the terms hydrophilic and hydrophobic to differentiate aqueous suspensions of markedly differing properties, as typified by gelatin and the colloidal metals respectively. These differ in many ways, the most striking being in their stability to salts and reversibility after precipitation. A gelatin solution, for example, is only precipitated by high concentrations of salts and after drying will readily take up water again. A sol of a metal, or of an insoluble salt like  $As_2S_3$ , is precipitated readily by traces of salts and does not return to the colloidal state, even if the salts are eliminated by washing the precipitate. This explains the indications reversible for hydrophilic and irreversible for hydrophobic systems. To cover dispersion media other than water, the terms lyophilic and lyophobic were proposed by Herbert Freundlich.

The early years of the 20th century witnessed many striking developments in physics and chemistry, many of which bore directly upon colloids; for example, the electronic structure of the atom and its bearing upon valency, the ideas of molecular size and shape as revealed by X-rays and the nature of solutions, to mention only a few. In addition, powerful new methods for studying the size and shape of colloidal particles were developed, such as the ultracentrifuge, electrophoresis, diffusion, the scattering of light and of X-rays, etc.

The study of interfaces, a topic clearly of great relevance to colloids, developed into a major field under the title of surface chemistry. The investigation of colloids in industry and biology also led to major developments in such fields as detergents, dyes, proteins, polymers, etc.

The main classification of colloids is that into reversible and irreversible systems. In the latter systems, to which belong sols (dilute suspensions), emulsions, foams, pastes (concentrated suspensions) and certain types of gels, the size of the particles is dependent greatly upon the method of preparation. In the reversible systems particle size is either given by the molecular size of the colloidal material, as in polymers, polyelectrolytes, proteins, etc., or the particles are formed from small molecules by a reversible association, as in soaps, detergents and certain dyes. Some of the important aspects of these diverse systems are outlined below.

## II. IRREVERSIBLE SYSTEMS

**1. Lyophobic Sols (Dilute Suspensions).**—Lyophobic sols are dilute systems; some typical examples, such as colloidal metals, silver chloride and prussian blue, have already been mentioned. Of suspensions in gaseous media (aerosols) some, such as fogs, mists and smokes, are well known; others, such as air-borne suspensions of bacteria, viruses and molds, are less obvious but of equal importance. Smokes have found considerable use in wartime for camouflage and antipersonnel purposes. The peacetime uses of aerosols include insecticidal sprays and frost prevention in orchards by means of smudge pots. The removal of smokes still presents a major industrial problem. In the electrostatic precipitator, one of the best-known methods, the smoke passes between wires charged to a high potential difference; because of the charges which they carry, or which are induced upon them, the smoke particles are attracted to the wires and thereby removed.

Dilute suspensions are known in all the three possible dispersion media (gas, liquid and solid), of which only those in air and in aqueous solutions can be considered here. The dispersed particles are almost invariably composed of a large number of atoms or molecules, and are usually visible in the ordinary or ultramicroscopes (about 100 Å—about 10  $\mu$ ). The amount of dispersed phase is always small, usually much less than 1%.

Suspensions can be prepared by breaking down particles of macroscopic dimensions (dispersion) or by growth from molecular or atomic units (aggregation) until particles of the requisite colloidal dimensions are obtained.

Dispersion is usually carried out in the laboratory by grinding in an agate mortar, commercially by means of a colloid mill in which the mixture of coarse particles and dispersion medium is subjected to intense shearing forces between a rotor and stator (a protective colloid is frequently added to prevent the colloidal particles from reaggregating). As first shown by G. Bredig, metals can be dispersed in liquids by striking an electric arc between them, usually in the presence of a trace of sodium hydroxide to stabilize the sol formed. In some cases dispersion can be brought about by adding a small amount of a third substance termed a peptizing agent. Examples are the peptization of clays by alkalis (caused by  $\text{OH}^-$  ion) and many finely divided precipitates by soaps or other hydrophilic colloids.

In aggregation processes the first step is to form a supersaturated solution, by chemical or physical means. This leads to formation of nuclei that grow to colloidal size and that have then to be stabilized in order to prevent flocculation. An example of a chemical process is the reaction between arsenic oxide and hydrogen sulfide in very dilute solution,  $\text{As}_2\text{O}_3 + 3\text{H}_2\text{S} \rightarrow \text{As}_2\text{S}_3 + 3\text{H}_2\text{O}$ , in which the insoluble arsenic sulfide appears in the form of minute particles dispersed in the aqueous solution. A common physical method is typified by the formation of sulfur sols by pouring a solution of sulfur in alcohol into water. Mist, fog and clouds are aerosols formed by physical means—rapid cooling of air saturated with water vapour.

The size of the particles formed in aggregation processes is determined by the ratio of nucleation and crystal growth. A high rate of nucleation is imperative for the formation of small particles.

**Liesegang Rings.**—Another phenomenon, named after its discoverer, R. E. Liesegang, where nucleation plays an important role is observed if an insoluble precipitate is formed during the diffusion of one reactant into the other. If, for example, a thin layer of dilute potassium dichromate in a gelatin gel is placed on a glass plate and a crystal of silver nitrate is placed at the centre, a periodic precipitate of insoluble silver chromate is eventually formed, as shown in fig. 1.

Each band is formed when a certain supersaturation has been reached locally, so that nucleation occurs. By subsequent growth of the nuclei the concentration is lowered also in the neighbourhood of the band, and the diffusion of  $\text{AgNO}_3$  can proceed a certain distance before a sufficient degree of supersaturation is again reached and the next band precipitates.

These bands are very similar to the banding in some minerals, such as agate, and are believed to explain such formations.

**Stability.**—As has been mentioned earlier, the stability of sols

arises chiefly from the charges carried by the particles preventing contact under conditions such that collision would otherwise occur. The charges are usually obtained by the preferential adsorption of one type of ion, often a negative ion, since most sols are negatively charged. When the sol particles are close together, attractive forces of the same nature as the London-Van der Waals forces in gases make themselves felt.

Addition of inorganic salts, which effectively screen the charges on the colloidal particles, leads to a reduction of the range of the electrical repulsive forces so that the attraction becomes predominant and coagulation follows. It has been possible to explain the Schulze-Hardy rule (see above) on this basis.

**2. Emulsions.**—The term emulsion is used to denote any stable colloidal dispersion of one liquid in another, but in practice only oil and aqueous solutions need to be considered, since biological emulsions, as well as those of most domestic and industrial importance, contain an oil and some aqueous solutions as the two immiscible phases. In order to attain the requisite degree of stability a third component, in addition to the oil and aqueous phases, is necessary. This component is termed the emulsifying agent, and is usually present in amounts of about 1%–5%.

Emulsions can exist in two types, oil-in-water (denoted by O/W) and water-in-oil (W/O), depending upon whether the aqueous or the oil phase is the continuous one. Two fundamental problems arise therefore—the origin of the stability induced by the emulsifying agent and the reason why some agents promote O/W and others the inverse type.

The subject of the technical and biological aspects of emulsions is a vast one. The principal technical uses are in pharmacy and cosmetics (creams and ointments are usually emulsions), in food preparations (e.g., salad cream, mayonnaise, margarine) and in many industries, particularly leather, textiles and paper. Margarine, for example, is a W/O emulsion stabilized by about 1% of oxidized soybean oil; mayonnaise and salad cream are emulsions of edible vegetable oils in aqueous solutions of edible acids stabilized by egg yolk.

Oils are often emulsified commercially. The three main reasons are dilution of the oil, increase in area of interface and modification of physical properties. Dilution effects economy of the oil (e.g., polishes, oil-soluble insecticides) by spreading it over a larger surface. Increase in area of interface may accelerate some chemical reactions (e.g., polymerization of vinyl compounds, hydrolysis of fats in soap manufacture). Modification of physical properties includes removal of objectionable characteristics; for example, emulsification diminishes the taste or smell of pharmaceutical preparations such as cod-liver oil and increases the fluidity of heavy oils such as tar. On the other hand, crude petroleum is frequently produced as a W/O emulsion. Breaking of this emulsion is often difficult but necessary before further processing.

In evaluating the stability of emulsions, creaming, coagulation and coalescence should be distinguished. Creaming is the accumulation of the droplets (usually at the top of the emulsion) under the influence of gravity. Small drops cream much more slowly than large ones. In coagulation the droplets come together forming aggregates in which the original drops are still separated. Coagulation enhances creaming. Coalescence means that the drops unite to form a continuous phase. Fresh milk creams markedly in a few hours. By acidification it can be made to coagulate. Coalescence is strongly increased by churning.

Emulsification is achieved by intense agitation of the mixture. On the small scale this can sometimes be done merely by hand shaking, but it is more usual to force the coarse emulsion under pressure through some type of valve, as in the household "cream machine." Industrially various types of colloid mill are used, in which the emulsion is subjected to very intense shearing forces, finally passing through a homogenizer. These treatments decrease the particle size and so increase the stability. (Milk is frequently homogenized in order to diminish creaming.)

The principal emulsifying agents are as follows: for O/W emulsions—proteins, gums, carbohydrates, natural and synthetic soaps, clays and certain hydrated oxides, particularly of silica or aluminum; for W/O emulsions—heavy metal salts of the fatty acids

FIG. 1.—LIESEGANG RINGS OF SILVER CHROMATE STRIKINGLY RESEMBLE THE BANDING IN MANY MINERALS, SUCH AS AGATE, AND ARE BELIEVED TO EXPLAIN THE MINERAL FORMATION

(e.g., zinc stearate, nickel oleate), long-chain alcohols such as cetyl alcohol, long-chain esters such as glycerol monooleate, oxidized oils, soot, lampblack, graphite, etc.

Various theories have been advanced to explain emulsion type, the most obvious being that originally suggested for solid powders. As fig. 2 shows for idealized spherical particles, if the solid is preferentially wetted by one phase then more particles can be accommodated if the interface is convex to that particular phase, and in an encounter between two droplets actual contact between the liquid in the drops is prevented, so that coalescence cannot occur. In other words, preferential wetting by water should tend to give O/W emulsions as in fig. 2(A), preferential wetting by oil the inverse type as in fig. 2(B). This is in agreement with the above list of emulsifiers, those promoting O/W emulsions being all hydrophilic whereas those that favour W/O are more oleophilic. It must be realized that other factors also enter, in particular the relative amounts of oil and water and even the order in which the phases are mixed.

The natural and synthetic soaps soluble in water are among the most widely used O/W emulsifying agents. Certain synthetic soaps (see *Association Colloids [Soaps and Dyes]* below) are often preferable to ordinary fatty acid soaps, as they are not precipitated by calcium ions and so can be used with hard water. The electric charge obtained by the oil drops by adsorption of the soap ions is one factor in stability; the mechanical properties of the adsorbed film seem to be another one. The strong reduction of the interfacial tension, which may become as low as 0.1 dyne/cm., facilitates emulsification greatly.

As previously mentioned, di- and trivalent fatty acid salts (e.g., nickel oleate) are efficient emulsifiers for the W/O type. In these systems the interfacial film consists of solid particles or a poly-molecular skin rather than a monolayer. A simple experiment to illustrate phase inversion is to prepare an O/W emulsion stabilized by sodium oleate and to add a few drops of saturated magnesium chloride. On being shaken the system inverts to the W/O type because of the magnesium oleate formed by double decomposition.

Proteins and gums normally only promote the O/W type of emulsion. A great variety of proteins are used commercially, such as egg albumen, dried blood, casein (from milk), etc., and proteins are wholly or partly responsible for the stability of many natural emulsions such as milk and rubber latex. Food emulsions are frequently stabilized by proteins, gelatin, etc. The stabilizing action of these substances arises from the mechanical protection given by the adsorbed skins which form spontaneously and which are relatively impenetrable for oil.

**3. Foams.**—A foam is a gaseous dispersion (usually of air) in a liquid continuum. Pure liquids do not give stable foams and for any reasonable stability a third component, the foaming agent, is essential. Of the great variety of substances that act as foam promoters the best known are the soaps (natural and synthetic), proteins including gelatin and other degraded proteins, certain finely divided solid powders, certain polymers and the saponins.

Household soap, which consists chiefly of a mixture of sodium stearate ( $C_{17}H_{35}COONa$ ) and sodium palmitate ( $C_{15}H_{31}COONa$ ), is well known for its bubble-blowing capacity. This property is greatly improved by the addition of glycerol, which probably acts

by increasing the viscosity of the film. An excellent composition for blowing stable bubbles is as follows: 28.2 g. oleic acid, 100 ml. N.NaOH, 300 ml. glycerin, 1,200 ml. distilled water. Many synthetic soaps, sodium cetyl sulfate ( $C_{16}H_{33}SO_4Na$ ), for example, are equally effective, with the added advantage that their lathering power is not so readily diminished by hard water (see *Association Colloids [Soaps and Dyes]* below). The thinning of a soap bubble is well known to be accompanied by the development of interference colours, the final films being black with thicknesses a small multiple of the ultimate one, which has a thickness of about 50 Å.

Stabilization of foams arises mainly from the same factors that govern the stability of emulsions. Indeed as to polarity a suspension of air bubbles in water (a foam) is very similar to a suspension of oil droplets in water. In both cases we find the same type of stabilizers.

Proteins find a wide use as foaming agents, because of their edible nature, in foodstuffs such as whipped cream, marshmallow (made from gelatin and sugar) and meringue (from egg white) where the foaming agent must be edible or at any rate nontoxic. The "firefoam" used to combat oil fires consists of bubbles of carbon dioxide (liberated from sodium bicarbonate and aluminum sulfate) stabilized by dried blood, glue or any other cheap protein-containing materials. Beer froth is believed to be stabilized by the colloidal constituents present, which include proteins and carbohydrates.

Saponins are noted for their foaming capacity and as obtained commercially from various plants are complex mixtures. They form rather solid surface films to whose mechanical strength their foams owe their stability, just as in the case of proteins.

Of the polymers with foaming power for aqueous solutions, the most important are methyl cellulose (water-soluble type) and polyvinyl alcohol (see *Polymers* below).

Certain finely divided solids, particularly if they have a waxy or hydrophobic surface, such as aluminum stearate or heavy metal soaps insoluble in water, remain at the air/water interface on agitation and stabilize the foam so formed. By suitable treatment many other materials can be made to behave similarly, and this forms the basis of the "froth-flotation" method for separating minerals. The structure of a single bubble in a foam stabilized by a fine powder is quite similar to that of the emulsion droplet represented in fig. 2(A).

Foaming may often be an undesirable property, as in lubricating oils, and its prevention is not always easy. Aqueous foams can usually be broken by spraying with small amounts of certain alcohols (e.g., amyl, octyl) or fatty acids.

**4. Pastes (Concentrated Suspensions).**—Pastes are concentrated dispersions of fine solid particles in a liquid continuum. From the practical point of view they are of extreme importance, covering such diverse materials as paints, putty, clays, dough, drilling muds, tooth paste and so on. These materials are all noted for their peculiar and characteristic mechanical properties, as denoted by such terms as plasticity, ductility, moldability, etc. The study of the flow and deformation properties of pastes, which are so vital in their practical usage, belongs to the science rheology.

The flow behaviour of a paste is determined not only by the volume concentration of the solid particles but also by their size and shape, their size distribution and by the colloidal stability of the suspended particles. At a given solid concentration a flocculated paste may be stiff and plastic whereas a stable or deflocculated one may be easily pourable. Examples of flocculated systems are very polar compounds in organic media (e.g., silica, calcium carbonate and other inorganic salts in oils such as benzene), or nonpolar substances such as carbon black in polar media such as water. Such systems can be rendered deflocculated by suitable additives, a practical example being the addition of aluminum stearate to inorganic paints in their oil vehicle. By such means a higher concentration of disperse phase can be obtained without increasing the consistency of the material or, alternatively, an increase in pourability at the same solid concentration. It is for the former reason that materials such as sodium silicate are added to potter's clay, since the water present, having ultimately to be re-

FIG. 2.—SOLID POWDER AT AN OIL/WATER INTERFACE SHOWING (A) HOW PREFERENTIAL WETTING BY OIL TENDS TO GIVE WATER/OIL EMULSIONS AND (B) HOW PREFERENTIAL WETTING BY WATER TENDS TO GIVE OIL/WATER EMULSIONS

moved, should be kept to a minimum. Putty is a paste of finely ground whiting (natural calcium carbonate) in a medium of linseed oil, its characteristic property being termed "string." Pure calcium carbonate and acid-free linseed oil give a friable putty without string, the system being a typical flocculated one. After adding small amounts of free fatty acid to the oil and of oxides of aluminum or iron to the calcium carbonate, the system is deflocculated and possesses excellent string. The desirable properties of the usual commercial material are therefore believed to arise from reaction between traces of these oxides and of fatty acids in the oil, forming a metal soap which deflocculates the system.

Pastes, particularly those with the higher concentrations of disperse phase, usually show some sort of yield value upon deformation. This is clearly essential if the material is to exhibit plastic properties (*e.g.*, potter's clay), since it has to retain its shape against the forces of gravity.

Certain pastes exhibit the phenomenon known as thixotropy; *i.e.*, after stirring or shaking they become much thinner in consistency, returning to their original state on being allowed to stand. A well-known example is quicksand, which consists of a paste of sand and water made thixotropic by the presence of certain clays.

Paint should be thixotropic in order to flow easily under the brush and to allow the brush streaks to disappear. After a short time it should solidify to prevent the paint from flowing away from vertical planes.

The reverse phenomenon, termed dilatancy, in which a suspension that flows freely under a small force turns rigid when larger forces are applied, is shown by very concentrated, highly stabilized suspensions; *e.g.*, by pastes of pure silica in water.

**5. Gel Structures.**—A flocculated paste or suspension of very fine particles often behaves as a gel; *i.e.*, a quasi-homogeneous solidlike system, rich in liquid. During the flocculation a scaffolding structure is formed preventing sedimentation and enmeshing the dispersion medium. Such structures are preferentially formed by long or flat particles. The systems are often thixotropic, the bonds between the particles can be broken by mechanical action. They show syneresis; *i.e.*, in the long run the scaffolding retracts by further flocculation and liquid is exuded.

Examples are: certain clays, particularly bentonite (flat particles), iron hydroxide (flat), vanadium pentoxide (needles). Those from iron hydroxide are reddish brown and become more transparent when liquefied.

In some cases gels are formed directly by chemical reaction. Substances that tend to separate as amorphous precipitates frequently give gels when first formed, the hydroxides of aluminum, chromium and silicon being good examples. Of these, the formation of silica gel by reaction between sodium silicate (water glass) and acids, or between silicon tetrachloride and water, has been much studied. The sol first formed slowly transforms spontaneously into a translucent gel showing bluish opalescence, and this gel may later shrink, exuding the aqueous medium (syneresis). The changes are believed to arise from the polymerization of the monosilicic acid first formed; *e.g.*,

It is clear that the process can be repeated in one, two or three dimensions, leading to high molecular weight silicic acids and a rather rigid three-dimensional gel.

Silica gel undoubtedly owes its high mechanical strength to the linking of the silicic acid molecules through primary valence

bonds ( $-\text{Si}-\text{O}-\text{Si}-\text{etc.}$ ), this also explaining the absence of

thixotropy, the irreversibility of the gelling process and the comparatively small effect of drying on the gel volume.

With the thixotropic types, where the gel structure can be easily and reversibly produced, it seems improbable that primary valence

bonds can be involved in linking the particles together. The most plausible theory is that the particles are linked at the points of contact through weak, secondary valence forces, the same forces that are active in ordinary flocculation.

**Ion Exchange or Base Exchange.**—A property of clays of great importance in agriculture is termed base exchange or, more correctly, ion or cation exchange. If, for example, a salt solution such as potassium sulfate percolates through a soil, the potassium ions are removed and replaced by an equivalent amount of calcium ions originally present in the clay.

Ion exchange also forms the basis of the zeolite or permutite water-softening process. In this case calcium ions are replaced by sodium ions and the water is thus softened.

Clays, the finest ( $< 2 \mu$ ) mineral constituents of the soil, consist of layer structures of aluminosilicates in which some cations of low valency are easily accessible and exchangeable. The nature of these ions is not critical for maintaining the clay structure; only their total electric charge is important.

Zeolites are essentially infinite three-dimensional frameworks as in the various forms of silica ( $\text{SiO}_2$ ), except that some of the Si atoms (often about one-half) are replaced by Al atoms. This replacement of Si by Al makes the framework negative and equivalent cations are taken up in the interstices to maintain electrical neutrality. Permutite (sodium permutite) has the approximate composition  $\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_8 \cdot 6\text{H}_2\text{O}$ . It is manufactured in various ways, such as by fusing a mixture of sodium carbonate, china clay or alumina and silica (sand, quartz, etc.), the resulting vitreous mass being then leached with water.

### III. REVERSIBLE SYSTEMS

Reversible colloids are characterized by the fact that colloidal solutions or gels can be formed spontaneously when the dry colloid and the dispersion medium are brought together. The size of the particles in reversible colloids is determined by the molecular weight of the colloidal material in the case of polymers or by reversible association in the case of detergents, certain dyes and a few other substances.

**1. Polymers.**—Polymers are high molecular weight substances built up of a large number of identical (or practically identical) repeating units, the single molecules being of colloidal dimensions. Nature has always made considerable use of polymeric materials, such as cellulose in wood and plants and proteins in horn, hair, wool, etc. The synthetic polymer industry began to grow rapidly in the 1920s, and plastic became a household word.

In nature three different functions of polymers can be distinguished. They serve as building materials (cellulose, proteins of skin and muscle), storage substances (starch, glycogen) and they play a fundamental role in biochemical reactions (enzymes, nucleic acids, genes). These functions are clearly related to the high molecular weight of these substances. The primary valence bonds in organic molecules are quite strong, not inferior to the bond strength in inorganic molecules. The secondary bonds, however, between organic molecules are weak and can be easily disrupted. Crystals of organic substances of low molecular weight as a rule are soft. Consequently a structure built of organic materials should contain a high proportion of primary bonds and this can be realized by building the structure with polymers. The advantage of using organic materials is that they can be "processed" at much lower temperatures than inorganic materials like metals or ceramics. In synthetic plastics man uses the same principle, although as a rule with other substances.

Polymers are used for storage purposes because for similar chemical structures the solubility is lower the higher the molecular weight.

The intricate functions necessary to regulate biochemical reactions including reproduction can, of course, be more easily incorporated in large than in small molecules, because the large molecules allow more diversification.

Most polymers, both natural and synthetic, are linearly built. In solution and often even in the dry state this long chain is folded or coiled. In proteins the folding is very regular. In synthetic polymers and in many natural ones like rubber and gums the

coiling is very irregular and determined by chance rather than by some building principle. One speaks of "statistical coils." The large extension in solution of polymer molecules is the cause of a high viscosity, which can be used for determining the molecular weight of the polymer.

When linear polymers are interconnected locally, a cross-linked polymer network is obtained. Such a network, when deformed, tends to return to its original shape because that was the situation of most probable coiling. This tendency explains both rubber elasticity and swelling of dried polymer gels.

For the purposes of discussion polymers are usually subdivided, according to their origin, into natural and synthetic, although an intermediate class, man-made derivatives from natural polymers, is also convenient. Some of the more important members of these three subgroups are as follows:

1. Natural polymers: cellulose, starch, rubber, proteins, the products from linseed and other "drying" oils.

2. Derivatives from natural polymers: nitrocellulose, cellulose acetate, regenerated cellulose (viscose, cellophane, etc.), vulcanized rubber.

3. Purely synthetic polymers: nylon, polystyrene, polythene, synthetic rubber, silicones, phenol-formaldehyde and urea-formaldehyde resins.

**Natural Polymers.**—Cellulose is the principal building constituent of the plant kingdom. Paper is derived from wood pulp, after treatment to separate the cellulose from the lignins and other substances present.

Cotton and flax, widely used in the textile industries, are almost wholly cellulose.

The cellulose molecule was shown by W. N. Haworth and others to consist of a linear array of condensed glucose units. (*See CELLULOSE: Chemical Constitution.*) The chain length or degree of polymerization depends upon the source and the method of extraction. The chain may reach a length several thousand times that of the monomer.

Starch is also of great importance in the plant world, not as a building material but as a convenient means of storing glucose, and hence energy and food; wheat, maize and other grains consist largely of it. It resembles cellulose in being a polycondensation product of glucose, but differs in having a branched-chain structure rather than a straight-chain one. Starch can be dispersed in hot water and is then used as a household material for laundry purposes. In the laboratory it is well-known for its blue coloration with iodine, a very sensitive test much utilized in volumetric analysis.

Natural rubber is a linear polymer built up from isoprene units, having the structure:

The repeat unit is shown between the dotted lines. Rubber is obtained naturally in the form of a milky suspension or latex from a wide variety of plants and trees. Commercially the genus *Hevea* is grown on a vast scale in Malaya and Indonesia, and forms the principal source of supply. The loss of these territories to the Japanese in World War II gave an enormous impetus to synthetic rubber production (*see below*).

After the latex has been coagulated by adding acetic acid or in other ways, the resulting "crepe" rubber is usually compounded with other materials to make it suitable for industrial use. For example, in the manufacture of tires it is compounded with carbon black, certain inorganic fillers such as zinc oxide and sulfur, and then subjected to heat treatment.

The action of sulfur leads to vulcanization, as it is termed, which is the formation of cross links between the chains through one or more sulfur atoms. Vulcanization makes the product more resilient and less liable to plastic flow.

Paints usually consist of a fine dispersion of an inorganic coloured powder (e.g., lead chromate, zinc oxide) in an oily medium

containing unsaturated glycerides such as linseed oil. These oils, when exposed as a thin film to the action of air, rapidly oxidize and polymerize, forming a protective skin for the underlying material and the pigment.

**Derivatives from Natural Polymers.**—Cellulose forms the basis from which several important substances are derived.

Nitrocellulose, or cellulose nitrate as it should more appropriately be termed, is the nitric acid ester of cellulose, made by treating cotton or other cellulosic materials with a mixture of nitric and sulfuric acids. If fully nitrated a trinitrate is obtained, each  $-\text{OH}$  group in the original glucose subunit having become  $-\text{O}.\text{NO}_2$ . Depending upon the degree of nitration the properties vary considerably, the higher members being used as propellants (e.g., cordite), the lower ones for lacquers, Celluloid, etc. Celluloid, the oldest commercially made plastic, consists of a mixture of cellulose nitrate with camphor, the latter being termed a plasticizer since it enables the polymer to be more readily worked. The major disadvantage of Celluloid is, of course, its inflammability.

Cellulose acetate, the acetic acid ester, is made on the larger scale for artificial silk, for lacquers and for safety film (because of its comparative inertness).

Cellulose can be dissolved in a number of solvents from which it can be precipitated more or less unchanged. Common forms are cellophane, widely used as a transparent waterproofing film, and viscose rayon, the oldest and still widely used artificial silk.

**Purely Synthetic Polymers.**—The science and the production of purely synthetic polymers was greatly developed during World War II. Synthetic rubber was and is still made on a large scale by copolymerizing a mixture of butadiene ( $\text{CH}_2=\text{CH}-\text{CH}=\text{CH}_2$ ) and styrene ( $\text{C}_6\text{H}_5-\text{CH}=\text{CH}_2$ ), both of synthetic origin. This gives a linear polymer resembling in many ways natural rubber. Nylon is made by condensing diamines with dibasic acids, a typical member having the structure  $-\text{NH}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{NH}.\text{CO}.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CO}-$ , etc. This structure has a close resemblance to that of natural silks and other fibrous proteins.

Many other types of polymers are made by polymerization of vinyl compounds (*i.e.*, compounds containing active double bonds), for example,

polythene ( $-\text{CH}_2.\text{CH}_2.\text{CH}_2.\text{CH}_2-$ , etc.),  
polyvinylchloride ( $-\text{CH}_2.\text{CHCl}.\text{CH}_2.\text{CHCl}-$ , etc.),  
polymethylmethacrylate (perspex or Plexiglas)

polyvinylalcohol ( $-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}-$ , etc.)  
 $\text{OH} \qquad \qquad \text{OH}$

The silicones are polymers based upon a silicon-oxygen chain. A member of this series would be:

They are much more stable to heat, organic solvents and chemical reaction than are the older plastics and should thus find many uses.

Finally, mention must be made of the well-known type of polymer Bakelite, made by heating phenols or urea with formaldehyde. These are cross-linked polymers and are termed thermosetting, since once formed they do not soften when warmed, in contrast with the above linear polymers which are thermoplastic; *i.e.*, they soften upon warming and harden again upon cooling. (*See also POLYMERIZATION.*)

**Polyelectrolytes.**—Polymers carrying a large number of ionizable groups deserve special attention. An example of these so-called polyelectrolytes is polyacrylic acid, a long-chain polymer with a carboxylic group on every other carbon atom of the chain.

Many natural polymers, as gum arabic, agar and proteins, are also polyelectrolytes.

Because of the mutual repulsion between the ionized groups, the form of the coil of a linear polyelectrolyte depends greatly upon its degree of ionization. Viscosity and swelling increase strongly with ionization.

**2. Proteins.**—A number of references to proteins, typical members of the hydrophilic class of colloids, have already been made. Proteins occur naturally in all living systems and are responsible for carrying out a great variety of vital functions. Many enzymes and certain viruses appear to be proteins. Tobacco mosaic virus, for example, can be prepared as a pure crystalline nucleoprotein which, nevertheless, has the ability to reproduce itself when injected into an uninfected plant. Nature not only utilizes proteins in the transport of insoluble materials, such as fat particles in milk, rubber particles in latex, oxygen in blood, but also as a means of building up rigid structures where mechanical strength is required. Most biological membranes consist, wholly or in part, of insoluble proteins or protein derivatives. Materials such as horn, hair, skin, cuticle, connective tissue and muscle are largely protein in nature. Gelatin and glue are breakdown products from complex proteins such as collagen.

It has long been known that proteins are essentially polycondensation products of  $\alpha$ -amino acids, of which glycine

$\text{CH}_3$   
|  
 $\text{H}_2\text{N} \cdot \text{CH}_2 \cdot \text{COOH}$  and alanine  $\text{H}_2\text{N} \cdot \text{CH}(\text{CH}_3) \cdot \text{COOH}$  are the simplest members. The structure of the polypeptide chain can be written

$\text{R} \qquad \text{R}^1$   
|        |  
 $-\text{CO} \cdot \text{NH} \cdot \text{CH} - \text{CO} \cdot \text{NH} \cdot \text{CH} \dots$  etc. where R and R<sup>1</sup> represent different side chains such as  $-\text{H}$ ,  $-\text{CH}_3$ ,  $-\text{CH}_2 \cdot \text{C}_6\text{H}_4\text{OH}$ ,  $-\text{CH}_2 \cdot \text{CH}_2 \cdot \text{NH}_2$ ,  $-\text{CH}_2 \cdot \text{COOH}$ , etc.

Proteins can be classified in various ways—for example, according to their degree of complexity, their size and shape, solubility or other physical properties, origin, etc.

Classified on the basis of complexity, proteins are divided into those which contain only  $\alpha$ -amino acids (e.g., egg albumen, the chief constituent of egg white), and those which contain additional groups (e.g., hemoglobin, the red pigment of blood responsible for oxygen transport, where the protein part of the molecule is linked to hem, a porphyrin). "Derived proteins" would, as the name implies, include such materials as gelatin, glue and proteoses, obtained by the partial decomposition of more complex proteins.

On the basis of shape, proteins are frequently classed as globular or fibrous, the former having a corpuscular shape (e.g., hemoglobin, egg albumen), sometimes approximately spherical, the latter being very much more elongated (e.g., myosin, an important constituent of muscle). Two other important fibrous proteins—both insoluble—are keratin (of which hair and wool are largely composed) and fibroin (the chief constituent of natural silk). Under some conditions (e.g., strong urea solutions) globular proteins can be unrolled, or denatured, forming fibrous proteins that after suitable chemical treatment can be spun into a material closely resembling wool.

In the early days proteins were largely separated by means of fractional precipitation with salts—those precipitated by half-saturated ammonium sulfate being termed globulins, whereas the albumins required fully saturated ammonium sulfate.

As pointed out earlier, salts differ very markedly in their ability to "salt out" proteins. For a given cation (e.g.,  $\text{K}^+$ ,  $\text{NH}_4^+$ ) the following sequence of anions in decreasing order of efficacy is found:

The last two—the iodide and thiocyanate—do not salt out even in saturated solutions. Alcohol can also precipitate proteins; added in subprecipitating amounts it renders them more readily coagulated by salts. In all cases precipitation occurs most readily at the isoelectric point (see below).

Of other physical properties of proteins a great deal of atten-

tion has been given to their size, shape and charge.

The size and shape of soluble proteins (and of other polymers in solution) have been chiefly found by measuring rates of diffusion and their rate of movement in very strong centrifugal fields. In the ultracentrifuge, developed largely by T. Svedberg at the University of Uppsala, Swed., the protein molecules are subjected to intense forces up to 1,000,000 times that of gravity. Under these conditions particles as small as 50 Å sediment at measurable speeds, whereas if only gravity were available nothing less than about 10000 Å (1  $\mu$ ) could be attempted. By such means the molecular weight and approximate shape of many proteins were determined, the former ranging from about 10,000 to several million. The single molecules are thus of sufficient size to bring them into the colloidal range. For example, hemoglobin has a molecular weight of about 68,000, hemocyanin (the respiratory pigment of certain snails) one of about  $5 \times 10^6$ . In both these cases the molecules are approximately spherical in shape, showing that the polypeptide chain must be folded in some way, whereas others, such as myosin, are quite elongated, with the polypeptide chain more or less fully extended.

Because of the presence of ionizable groups, particularly  $-\text{NH}_2$  and  $-\text{COOH}$ , protein molecules in solution normally carry a charge. In very acid solutions they are positively charged (because of  $-\text{NH}_3^+$ ), in very alkaline ones negatively (because of  $-\text{COO}^-$ ); at some value of the hydrogen ion concentration the net charge is zero. This value is termed the isoelectric point and is of considerable importance. It can be determined in various ways, usually by measuring the electrophoretic mobility in buffer solutions of different pH on both sides of the isoelectric point, plotting the results graphically, and reading off the pH of zero mobility. (See also PROTEINS.)

As different proteins contain different numbers of ionizable groups, their electrophoretic mobilities at a given pH are different. A. Tiselius of the University of Uppsala developed a technique of electrophoresis in which these differences in mobility are used for analytical or for preparative purposes.

**3. Gels.**—Several lyophilic colloids can form gels. Table jellies, blancmange and cold starch paste are well-known examples. These gels can all be considered as network structures with enmeshed liquid. The jelling component may be gelatin, agar, starch, pectin, etc., and is usually present in concentrations of less than 10%. Table jellies are usually made from gelatin (a protein) (2%–3%); jams are jelled by pectin (a carbohydrate derivative). Agar slopes or plates, widely employed in bacteriological work, consist of a suitable nutrient medium jelled by the addition of 1%–2% agar, a polymer of carbohydrate nature prepared from certain seaweeds. Fatty acid salts such as aluminum, calcium and zinc oleates are the thickening agents in many greases, which are examples of gels with a nonaqueous liquid phase. Some materials such as gelatin and agar set to a gel on cooling whereas in other cases gelation is brought about by heating (egg white). In both cases, however, gelation arises from a process akin to a diminution of the solubility of the jelling agent leading to the formation of interconnections between the individual molecules.

**4. Association Colloids (Soaps and Dyes).**—Soaps and other detergents and a number of dyes constitute by far the most important substances classed as association colloids; i.e., substances of relatively small molecular weight which associate spontaneously to micelles of colloidal size in certain concentration ranges.

**Soaps.**—Originally limited to substances of natural occurrence, a very great number of compounds have been prepared synthetically in view of their importance as wetting agents, emulsifiers, detergents, etc. A few typical soaps are given below, the classification into anionic, cationic and neutral types being based on the charge carried by the organic part of the molecule.

Compound	Formula	Type
Sodium palmitate	$\text{C}_{15}\text{H}_{31}\text{COO}^-$ and $\text{Na}^+$	Anionic
Sodium dodecyl sulfonate	$\text{C}_{12}\text{H}_{25}\text{SO}_3^-$ and $\text{Na}^+$	Anionic
Cetyl trimethyl ammonium bromide	$\text{C}_{16}\text{H}_{33}\text{N}(\text{CH}_3)_3^+$ and $\text{Br}^-$	Cationic
Polyethylene oxide derivatives; e.g.,	$\text{C}_{12}\text{H}_{25}(\text{OCH}_2\text{CH}_2)_2\text{OCH}_2\text{CH}_2\text{OH}$	Neutral

In addition, there are naturally occurring compounds such as the bile salts and lecithin, of great biological importance.

All these compounds (and the dyes also), despite their diverse chemical types, possess as common features a large hydrocarbon portion and a small polar group. These two parts differ to the extreme in their affinity for water, and it is this two-sided or amphipathic nature which leads to the formation of colloidal aggregates.

J. W. McBain and his co-workers showed that with aqueous solutions of the sodium and potassium salts of the fatty acids the higher members differed in certain physical properties from those with shorter chains. These higher members (*e.g.*, the palmitate or stearate) appeared to possess a smaller number of particles (as indicated by the freezing point or vapour pressure) but nevertheless a quite high electrical conductivity.

This combination led McBain to suggest that the paraffin-chain ions aggregated, forming a colloidal particle or ionic micelle, as shown in fig. 3.

In the case of sodium palmitate, for example, the size of the micelle, as determined from diffusion measurements, is about 40 Å and thus contains about 50 molecules, the molecular weight being about 14,000. In relatively dilute solutions the shape of micelles is spherical or slightly elongated. The opinions on the micellar form in concentrated solutions are conflicting and vary from a regular latticelike array of spherical micelles via very elongated rods or threads to flat structures.

Aggregation to micelles is caused by the tendency of the water to squeeze out the paraffin chains—the same factor that is largely responsible for the marked surface activity of soap solutions.

The characteristic features of soap solutions arise from the combination of surface activity and the peculiar properties of micelles in solution.

The power of soap solutions to dissolve (solubilize) organic compounds insoluble or only slightly soluble in water arises directly from the presence of micelles. As will be clear from fig. 3, micelles possess an interior closely resembling a droplet of liquid hydrocarbon, in which hydrocarbons, etc., can dissolve. One important application of this phenomenon is in connection with synthetic polymers, for it enables polymerization of relatively insoluble monomers such as styrene (see *Polymers*, above) to be carried out in aqueous solution or suspension.

The characteristic and most widely used property of soap solutions is, of course, their detergent action. "Dirt," in general, consists either of greasy materials or of particles covered with a greasy film. Its removal involves three separate stages—access of the detergent to the dirty surface, the loosening or peptizing of the dirt and finally its removal into the bulk of the solution.

Because of its greasy surface, dirt is hydrophobic and not wetted by water, but absorption of the surface-active soap molecules makes its outer surface hydrophilic and therefore greatly increases its affinity for water. In addition, the detergent, because of its powerful tendency to adsorb on all surfaces, will tend to displace the grease from the surface.

The dirt, thus loosened, is detached by mechanical agitation and carried away into the solution by an emulsion or suspension, or solubilized in the interior of the micelles.

The chief drawback of fatty acid soaps (ordinary household soaps) arises from their ready precipitation with calcium or magnesium salts. This is why hard water is softened and why it is impossible to get a lather in sea water with ordinary soap. Many of the synthetic detergents do not suffer from this disadvantage and thus are used in "sea-water soaps."

Ordinary household soap is prepared by boiling natural fats, glycerides of the higher fatty acids, with strong caustic soda solu-

tion. After hydrolysis is complete the soap is salted out by addition of common salt.

The potassium salts (soft soap) rather than the sodium are preferable for some purposes, since they have a higher solubility in cold water.

**Dyes.**—Dye molecules, although resembling the soaps in possessing a hydrophobic part and one or more polar groups, lack their comparative uniformity as regards the relative disposition of these constituent parts.

This results in the aggregation being much more specific and hence in a more varied colloidal behaviour. The structure of two of the simpler members is shown below.

Orange II

Methylene blue

Dyestuffs are usually classed as acidic or basic (corresponding to anionic or cationic soaps) according to whether the organic ion carries a negative or a positive charge.

The question of aggregation is of considerable importance in connection with the dyeing process. The size of the aggregates or micelles can be determined by the same methods as for soaps, diffusion being regarded as the best. The degree of association is increased by increasing salt content, which explains the influence of salts in dyeing.

The dyeing process has naturally excited considerable interest, although it is by no means fully understood. The materials to be dyed are usually of a fibrous nature, consisting of macromolecules of vegetable, animal or purely synthetic origin. Most vegetable fibres, such as linen and cotton, have cellulose as the fundamental constituent; wool and silk are the principal animal fibres and of the purely synthetic materials nylon is without doubt the best known.

In dyeing a fibre the coloured molecules have to diffuse into the interior, where they are held in position by precipitation or by some other reaction. The behaviour of wool and silk is probably the simplest, for the major factor in bringing about combination is believed to be salt formation between the dye anions  $-NH_3$  groups on the fibre. With cellulose (cotton and rayon) the affinity of the dye for the fibre is probably due to Van der Waals's forces and hydrogen bonding.

Dyes also find an important use in the identification of biological materials (*e.g.*, bacteria) by staining methods. These depend upon the different affinities of the enveloping constituents for various dyes, the principles involved being closely related to those in ordinary dyeing. Dyestuffs of the basic type (*e.g.*, gentian violet) find use as antiseptics, resembling the cationic soaps in their bactericidal powers.

**BIBLIOGRAPHY.**—Elementary textbook: Allen Gordon Ward, *Colloids, Their Properties and Applications* (1945); advanced textbooks: Albert Ernest Alexander and Paley Johnson, *Colloid Science*, 2 vol. (1949; reissued 1952); Hugo Rudolph Krut (ed.), *Colloid Science*, vol. i, *Irreversible Systems*, vol. ii, *Reversible Systems*, Eng. trans. by L. C. Jackson (1949-52). (A. E. A.; J. T. G. O.)

**COLLOT D'HERBOIS, JEAN MARIE** (1749-1796), French revolutionary, a Jacobin, terrorist and opponent of Robespierre, was born in Paris on June 19, 1749, the son of a goldsmith named Collot. Educated by the Oratorians, he became an actor and began writing comedies (including *Le Paysan magistrat*, *Le Bon Angevin*, *L'Amant-loup garou*). After managing the Lyons theatre (1787), he settled in Paris (1789) and won success with his plays at the Théâtre Feydeau. Joining the Jacobin club, he served several times as its secretary in 1791. To spread constitutional principles, he composed his *Almanach du Père Gérard*, which made him famous. A member of the Paris commune of Aug. 10, 1792, he became president of the Paris electoral assembly

AGGREGATED HYDROCARBON CHAINS

FIG. 3.—STRUCTURE OF A MICELLE FORMED BY THE AGGREGATION OF PARAFFIN-CHAIN IONS IN A SOAP SOLUTION

and then its deputy in the Convention. In Nov. 1792 he was sent to Nice to investigate the depredations committed by the Var army. He voted for Louis XVI's death without reprieve. Sent in March 1793 to the Nièvre and Loiret *départements*, he ordered that all priests be arrested. Having taken part in the overthrow of the Girondins (May–June 1793) and undertaken a mission to the Oise and Aisne *départements* (August), he was made a member of the committee of public safety on Sept. 6. Sent on Oct. 30, with Joseph Fouché, to suppress the revolt in Lyons, he accomplished the task with pitiless bloodshed. Recalled to Paris, he made a great show of energy and argued in favour of the Hébertists in the Jacobin club, emerging as a possible rival to Robespierre. An attempt on his life (May 23, 1794) enhanced his popularity. As president of the Convention he declared himself violently against Robespierre on 8–9 Thermidor (July 26–27, 1794), but charges were subsequently brought against him by the Thermidorians. After the abortive Jacobin rising of 12 Germinal (April 1, 1795), he was deported to Guiana, where he died on June 8, 1796.

(MA. BO.)

**COLLOTYPE** (PHOTOGELATIN), a photomechanical printing process capable of accurate facsimile reproduction. It differs from other methods such as letterpress, offset lithography and gravure in that no halftone screen is employed to break the images into dots. Collotype illustrations, therefore, resemble photographs more closely than do products of the other processes.

It is a planographic method; that is, the printing image is on the same plane as the rest of the plate. Collotype printing is based upon the principle that grease and water repel each other. The nonprinting areas of the plate contain the most moisture and therefore reject the greasy ink, while the printing areas hold little moisture and accept the ink.

Collotype is used where accuracy of detail is desired. The absence of screen pattern makes it suitable for large blowups and for reproductions of manuscripts, works of art and scientific illustrations. It is unexcelled for the reproduction of fine paintings. The process is used for small and medium editions, ranging from 100 to 10,000 copies.

The basic principle of collotype was described in Louis Poitevin's French patent of 1855. T. du Motay and C. R. Maréchal of France produced the first good results in 1865. It remained for Joseph Albert of Germany, however, to develop collotype as a practical process about 1868. It was improved in 1869 by Ernest Edwards of England, who added chromated alum (a mixture of alum and a chrome salt) to toughen the gelatin film. Edwards went to the United States in 1872 and was instrumental in making the process commercially successful. Edward Bierstadt, however, who was licensed to use Albert's process, produced the first collotypes in the United States in 1870. Edwards took out the first patent for colour collotype in England in 1869, but Albert invented the most practical early process, using three colours, in 1874.

Formerly, almost all collotype printing was done from glass plates inked by hand and printed on a flat-bed press. This method was largely superseded by the use of big rotary presses with automatic inking devices. In plate making, two negatives are made, one for the continuous-tone illustrations and another for the line copy (type, black-and-white copy). The plate, usually of aluminium, is coated in a whirling machine with a light-sensitive solution of gelatin, potassium bichromate and ammonia. It is exposed to light in a printing frame under each negative successively, or under a single negative made by combining both. The transparent parts of the negative allow light to pass freely, hardening the gelatin; darker areas retard light, preventing hardening in proportion to their opacity. The plate is then soaked in glycerin, which is absorbed most by the soft, nonprinting areas. In printing, the plate receives moisture from the air in the pressroom, which is kept at a relative humidity of 60%–80%. When the ink roller passes over the plate, the soft or nonprinting areas of gelatin, which hold moisture, repel the greasy ink. The hardened exposed areas, which cannot hold moisture, accept the ink. Intermediate areas accept ink in varying amounts.

Printing is done directly from the gelatin, which has a delicate natural grain. Tacky ink is used, and since this dries slowly,

it is necessary to slip-sheet each impression; that is, a sheet of absorbent paper or other material must be placed over each printed sheet to avoid offsetting ink to the sheet above.

Flat-bed presses produce about 1,000 impressions in an eight-hour day; cylinder presses can turn out 5,000 in the same period. The life of a collotype plate is short; it will rarely last for 15,000 impressions.

For colour work, the separations can be made by hand as well as by photography. In the hand method a single negative is made. A handmade mask or stencil is prepared for blocking out the unwanted areas in each colour separation. The same negative with a different mask is exposed over each plate. By this process colour plates can also be made from monochrome copy.

Collotype is also known as albertype, *phototypie*, *Lichtdruck*, heliotype and photocollotype.

A. Wilson, *The Practice of Collotype* (1935), a handbook for printers; William T. Berry, *Collotype Printing Process* (1958), a compact description of the process. (J. KA.)

**COLMAN, SAINT** (d. 676), the leader of the Celtic party at the synod of Whitby, was born in Ireland. He was a monk at Iona before becoming bishop of Lindisfarne in 661. After the Roman method of calculating the date of Easter was accepted at Whitby (663 or 664), he returned to Iona and then to Ireland with all the Irish monks of Lindisfarne and 30 of the English ones. He settled on Inishbofin, Connaught, where he built a monastery, but had to found a separate one at Mayo for the English monks. He was abbot of both until his death on Aug. 8, 676. His feast day is Feb. 18 in Scotland (diocese of Argyll and the Isles).

See *Butler's Lives of the Saints*, ed. by H. Thurston and D. Attwater, vol. 1, pp. 369–370 (1956).

**COLMAN, GEORGE**, the Elder (1732–1794), one of the foremost English writers of comedy and theatre managers of his time as well as an agreeable essayist, was born in Florence in April 1732. His father, Francis Colman, envoy to the grand duke of Tuscany, died in 1733 and the child became the ward of his uncle, William Pulteney (later earl of Bath). He went to Westminster school and Christ Church, Oxford, where he founded with Bonnell Thornton *The Connoisseur* (1754–56), to which he contributed many essays. Called to the bar (1757), he traveled the Oxford circuit from 1758 to 1761, but relinquished law for literature and the theatre.

His first play, the afterpiece *Polly Honeycombe* (1760), satirizing the craze for romantic novels, was presented by David Garrick at Drury Lane. It was followed by *The Jealous Wife* (1761), one of the best comedies of its age, which remained a stock piece for nearly a century. In his early plays he mocked the vogue for sentimentalism, later seeking to revive the Elizabethan dramatists and adapting Beaumont and Fletcher's *Philaster* (1763) and *Bonduca* (1778) and Jonson's *Epicæne* (1776) and *Volpone* (1782). He translated Terence's comedies (1765) and Plautus' *Mercator* for Thornton's edition (1767) and also contributed essays to various newspapers and periodicals.

In 1764 Lord Bath died, leaving Colman an annuity. Colman's association with Garrick culminated in their collaboration in *The Clandestine Marriage* (1766), a comedy blending satire with sentiment, which still holds the stage. In 1767 Colman purchased a quarter share in Covent Garden, which he managed for seven years. In spite of quarrels with his partners, he raised the standard both of acting and of drama, himself contributing several comedies and afterpieces and adapting Shakespeare plays. In 1774 he sold his share to his partners and in 1776 purchased the Little Theatre in the Haymarket from Samuel Foote: under his direction for 12 years, this summer theatre reached the peak of its career. Colman had a stroke in 1785 and in 1789 his brain became affected. He died on Aug. 14, 1794.

His *Dramatick Works*, four volumes (about half his plays), were published in 1777 and his miscellaneous writings in verse and prose, as *Prose on Several Occasions*, three volumes, in 1787. He also translated Horace's *Ars poetica* (1783).

See Eugene Page, *George Colman the Elder* (1935). (S. M. R.)

**COLMAN, GEORGE**, the Younger (1762–1836), English dramatist and theatre manager, son of George Colman the Elder (q.v.) and the actress Sarah Ford, who were subsequently married in 1767. He was born in London on Oct. 21, 1762, and went to Westminster school and Christ Church, Oxford, but because of his contraction of debts was removed to King's college, Aberdeen. Though a student at Lincoln's Inn, he never completed his legal studies. His first play, *The Female Dramatist*, presented at his father's Little Theatre in the Haymarket in 1782, failed, but his comic opera *Two to One* (Haymarket, 1784) was successful. His comic opera *Inkle and Yarico* (1787) and his melodrama *The Battle of Hexham* (1789) became stock plays. In 1784 he married the actress Catherine Morris at Gretna Green.

After his father's mental breakdown in 1789 he took over the management of the Haymarket, which he purchased on his father's death in 1794. His management was marked by struggles against the encroachments of the patent theatres, by litigation and extravagance. Several of his melodramas and comedies held the stage for many years, notably *The Iron Chest* (1796)—based on William Godwin's novel *Caleb Williams* (1794); *The Heir at Law* (1797); *Blue-Beard* (1798); *The Poor Gentleman* (1801); and his most popular comedy, *John Bull* (1803). He wrote several of his heroines for Mrs. Gibbs (née Mary Logan), whom he is said to have eventually married. His outstanding comic creation was "Dr. Pangloss" in *The Heir at Law*. Colman disposed of part of his interest in the Haymarket in 1805 but continued to act as manager until 1820, when he sold his share to his brother-in-law, David Morris. He published books of verse, some very scurrilous. As a result of monetary difficulties he was compelled to reside in the rules of the King's Bench for many years but was released on his appointment as lieutenant of the yeomen of the guard in 1820. He was appointed examiner of plays in 1824, a post he retained until his death and in which he aroused resentment owing to his narrow severity and petty tyranny. He died in Kensington on Oct. 17, 1836.

See George Colman, *Random Records* (1830); R. B. Peake, *Memoirs of the Colman Family* (1842). (S. M. R.)

**COLMAN, NORMAN JAY** (1827–1911), U.S. farm journalist and the first secretary of agriculture, was born May 16, 1827, near Richfield Springs, N.Y. After a short law career, he moved in 1852 to St. Louis, Mo., where he became editor-publisher of *The Valley Farmer* (called *Colman's Rural World* after 1865). Through its pages, he advocated better farming methods and disseminated knowledge of new techniques, some of which he publicized on his own farm. Colman entered the Missouri legislature in 1865 and after 1874 served a term as lieutenant governor. He supported numerous farm organizations, helping to establish the Missouri Grange in 1870.

Appointed U.S. commissioner of agriculture in 1885, he authored the Hatch act of 1887 which set up federal-state agricultural experiment stations. Pres. Grover Cleveland named him secretary of agriculture in 1889, when the department of agriculture received cabinet status for the first time, but he served only briefly because of a change of presidential administrations in the same year. He returned to St. Louis to edit *Colman's Rural World* until his death on Nov. 3, 1911. His periodical was absorbed by the *Journal of Agriculture* in 1916.

See G. F. Lemmer, *Norman J. Colman and Colman's Rural World* (1953). (C. C. J.)

**COLMAN, SAMUEL** (1832–1920), U.S. landscape painter, whose landscapes of the early west remain popular, was born at Portland, Me., March 4, 1832. He was a pupil of Asher Durand in New York city, and in 1860–62 studied in Spain, Italy, France and England. In 1871–76 he was again in Europe. With James D. Smillie, he founded the American Water Color society (1860), becoming its first president, 1866–67. His own water-colour paintings are particularly fine. He was elected a member of the National Academy of Design in 1862. Among his works are "The Ships of the Western Plains," in the Union League club, New York city, and "The Spanish Peaks, Colorado," in the Metropolitan Museum of Art, New York. He died in New York city, March 27, 1920.

**COLMAR**, a town of France, capital of the Haut-Rhin (q.v.)

*département*, stands on the Lauch and Logelbach, tributaries of the Ill, 67 km. (42 mi.) S.S.W. of Strasbourg by road. Pop. (1954) 45,453. Many notable Renaissance buildings surround the Roman Catholic St. Martin's church (13th and 14th centuries). They include the Kaufhaus (15th century), the Pfister house (1537) and several others. The former Franciscan church (13th century) is now Lutheran. The *Hôtel de Ville*, the Palais du Conseil and the college chapel of St. Peter are 18th century. Frédéric Auguste Bartholdi, sculptor of the Statue of Liberty erected at New York harbour, was born in Colmar in 1834; his home is a museum. The town library is in the former Dominican monastery. The Unterlinden Kloster, former convent of the Dominican nuns, was made into a museum containing fine 15th- and 16th-century paintings, including the masterpiece of Mathias Grünewald (q.v.), his Isenheim altarpiece.

Colmar is on the main railway from Strasbourg to Mulhouse and Basel. It is a centre of the textile industry and for tourism as well as marketing the products of the neighbouring vineyards and orchards.

Colmar (Columbaria) is first spoken of in a chronicle of the Saxon wars of Charlemagne, then mentioned in a charter of 823. In 1226 it was raised to the status of an imperial town by the emperor Frederick II and surrounded by walls. Civil rights (*Stadtrechte*) were granted to it by Rudolph of Habsburg in 1278. Colmar joined the league of imperial towns of Alsace and in 1476 and 1477 took a vigorous share in the struggle with Charles the Bold. It suffered in the wars of the 17th century, was occupied by the Swedes in 1632 and was gradually annexed to France during 1648–78 and to Germany in 1871, reverting to France in 1919. During World War II it was occupied by the Germans in 1940 and was liberated by the Allies on Feb. 2, 1945. (L. K. V.)

**COLOCYNTH** (COLOQUINTIDA or BITTER APPLE), a plant, *Citrullus colocynthis*, of the family Cucurbitaceae (q.v.), whose fruit yields a very powerful cathartic. The fruit is round and about the size of an orange; it has a thick, yellowish rind and a light, spongy and very bitter pulp, which contains the active principle, colocynthin. The seeds, which number from 200 to 300 and are disposed in vertical rows on the three parietal placentas of the fruit, are flat, ovoid and dark brown; they are used as food by some of the tribes of the Sahara, and a coarse oil is expressed from them. The foliage resembles that of the cucumber, and the root is perennial. The plant has a wide range, being found in Ceylon, the Indian subcontinent, Iran, Arabia, Syria, north Africa, the Greek islands, the Cape Verde Islands and southeast Spain.

The commercial colocynth consists of the peeled and dried fruit. In the preparation of the drug the seeds are removed from the pulp.

**COLOGNE** (Ger. KÖLN), a city and river port of Germany which after partition of the nation following World War II was in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. Situated 295 mi. W.S.W. of Berlin, it lies mainly on the left bank of the Rhine in the fertile lowland plain below Bonn. Pop. (1959 est.) 780,124.

Cologne's historic importance arose from its location at the crossing of the route from England, France and the Netherlands to eastern Europe with that between Italy and northwestern Europe—a route accentuated by the great traffic artery of the Rhine. The medieval commercial centre which grew up there was also a patron of learning and the arts, a tradition which has persisted into modern times.

Despite the destruction suffered by the city during World War II, its appearance still reflects its history. Cologne lies principally on the left bank of the Rhine in the semicircle which it assumed in 1180, when several new parishes were brought within the town boundaries. The flat side of the semicircle is bounded by the Rhine, which is spanned by five bridges. The half circle is formed by a great ring road, the Ringstrasse, which in the 1880s replaced the medieval fortifications and along which a green belt was laid out. Remains of the old walls may still be seen and three surviving gates, the Eigelsteintor, Hahnentor and Severintor, are used as museums for zoology, history and antiquities, and geology, respectively. The Bayenturm, a medieval tower, stands near

AUTHENTICATED NEWS

THEATRE AND OPERA HOUSE OF COLOGNE, GER., OPENED IN 1957; AT UPPER RIGHT IS COLOGNE CATHEDRAL, BEGUN IN THE MID-13TH CENTURY

the Rhine. Beyond the Ringstrasse modern suburbs have projected spurs but the main shopping and business streets such as the Hohestrasse and Schildergasse, as well as the city's historic buildings, lie within it.

Not far from the Rhine is the cathedral, the largest Gothic church in northern Europe. It stands on the site of a church begun in the 9th century by Hildebold, metropolitan of Cologne, and finished under Willibert in 873. After a fire in 1248, rebuilding was begun by Meister Gerard. The choir was completed in 1322, and work on the cathedral went on until 1510 when it is said that Renaissance contempt for the Gothic style brought building to a halt. Work was resumed in 1820 and the building was completed, according to the original design, in 1880. It was badly damaged during air raids on Cologne in 1944. Though poorly proportioned, the cathedral is impressive in its vastness, being 468 ft. long and 275 ft. wide. Its great twin towers rise over 500 ft. above the centre of the city. The 14th-century stained glass windows in the choir are particularly beautiful. The cathedral is also notable for the art treasures which it contains. On the high altar are the relics said to be those of the Magi, brought to Cologne from Rome in 1164 and preserved in a solid gold shrine which is one of the finest medieval examples of the goldsmith's art. The painting above the altar is the centre panel of a triptych by Stephan Lochner (*q.v.*). Painted in the early 15th century, it depicts the Adoration of the Kings in clear, bright colours and gold.

At the south side of the cathedral lies a reminder of Cologne's more ancient past—the Dionysian mosaic, originally the floor of the banquet hall of a great Roman villa discovered during excavations near the cathedral in 1941. Other Roman remains are a 3rd-century tower, Roman-Frankish catacombs and a Roman mausoleum in Weiden, in the outskirts. The cathedral itself is ringed with noble churches, largely built in the prosperous middle ages. St. Gereon is of late Roman origin, although the building is 11th–13th century. St. Maria im Kapitol, which was severely damaged in World War II, is Romanesque and has a particularly fine crypt. Both St. Maria and St. Kunibert, which is Byzantine-Moorish in style, date from the 7th century although the actual buildings are 11th and 13th century, respectively. Other medieval churches include St. Severin (10th–15th century), St. Andreas (13th century) with the tomb of Albert Magnus, St. Aposteln (13th century), St. Georg (11th century), St. Ursula (11th–15th century), Gross-St. Martin (12th–13th century), the Minoritenkirche (13th century) and St. Maria Lyskirchen (13th century). The 14th-century Antoniterkirche, a secularized monastery church, was made over to the Protestants in 1802 and became the first public Reformed church in Cologne. It contains a war memorial, the "Angel of Death," by the sculptor Ernst Barlach.

Cologne's secular medieval buildings as well as its churches suffered in World War II, among those damaged being the Templerhaus and the Gothic Rathaus. The Gürzenich or Festhaus of the merchants of the city (1437–44), reconstructed as a concert and

festival hall, and the 16th-century Zeughaus or arsenal, which contains a historical museum, were only outwardly restored in medieval form.

These ancient buildings share the crowded city centre with modern banking and insurance houses, shops and offices, a new theatre and opera house (opened 1957) and, immediately north of the cathedral, the great railway station and the radio station of the Nordwestdeutscher Rundfunk. Near the perimeter of the city is the new town hall. On the other side of the river are the Rhein museum and the Wallraf-Richartz museum, housing paintings and Roman antiquities. Two other important museums, both on the left bank, are the Schnütgen museum for ecclesiastical art and the Rautenstrauch-Joest ethnological museum. The University of Cologne, founded in 1388, was dissolved in 1798 during the Napoleonic Wars, and refounded in 1919. There are also teachers' training colleges and colleges for the study of music, engineering and administration. A sports stadium was built in the green belt just beyond the Ringstrasse. Among several parks are the zoological and botanical gardens to the north, the Stadtgarten and the Volksgarten, while on the other side of the river is the Rhine park with the Tanzbrunnen ("dancing fountain") and the halls where the many fairs and exhibitions are held.

Cologne's geographical position and commercial importance have combined to make it a focal point for communications. A great rail junction, it also has an airport in the Wahner Heide, and on the edge of the city centre there is a helicopter landing ground with services to Brussels, Liège, Maastricht and Bonn. The *Autobahn* connects Cologne with Aachen and with the Ruhr, Frankfurt and the south. The Rhine harbour, important since Roman days, is used even by small seagoing craft.

The city is still, as it was in the middle ages, a banking centre, and the wine trade and textile manufacturing remain prominent. In modern times, however, insurance became of great importance and engineering and electro-engineering, metals and chemicals came to the fore. Other manufactures include chocolate and the famous Eau de Cologne. The brown coal industry is the second largest in Germany and is the basis of an electricity plant which supplies not only large parts of west Germany but also Switzerland and the Tirol. An annual festival, part of the Rhenisch pre-Lenten Carnival, is celebrated with great ceremony in Cologne. A folk festival, the Kölscher Fasteleer, is peculiar to the city.

**History.**—Cologne was originally the central point of the settlement of a tribe known as the Ubii. It was a Roman camp as early as 38 B.C., and the beginnings of a town may be traced back to about 12 B.C. In A.D. 50, at the request of Agrippina, the wife of the emperor Claudius, the title of Roman colony was conferred upon the town which was her birthplace. It was named Colonia Claudia Ara Agrippinensis, contracted later to Colonia. At first governed by the admiral of the Rhine fleet, it was later made the headquarters of the governor of Lower Germany. About 400 A.D. Cologne was conquered by the Franks and in 475 became the residence of the Frankish king Childeric.

A Christian community existed in the town probably as early as the 2nd century, a bishop first being mentioned in 313. Charlemagne created an archbishopric there and by the 12th century the archbishop dominated the city politically and commercially, receiving a wide range of tolls, customs duties and other payments. Cologne's industry goes back to Roman times when ceramics and glass were manufactured, and, with steadily growing commercial prosperity during the middle ages (especially from about the 10th century), an increasingly bitter conflict developed between the wealthy merchants and the archbishop, the former seeking commercial and political freedom, the latter the preservation of his temporal power. In 1074 Archbishop Anno was expelled but the revolt was put down. It was not until the battle of Worringen in 1288 that the archbishop was finally defeated and the city of Cologne secured full self-government. The battle was fought in the course of the struggle over the Limburg succession (*see LIMBURG, DUCHY OF*). From that time Cologne was in fact a free imperial city, although it was only officially recognized as such in 1475.

Until the end of the 14th century its government was in the

hands of the Richerzeche, an association of the wealthy patricians, but in 1396, after a bloodless revolution, a new municipal constitution was established (embodied in the *Verbundbrief*). Under this constitution the 22 branches of the guilds were the basis of the government. They in turn elected a council which had power over all the internal affairs of the town.

This medieval period was a splendid one for Cologne. It was a prominent member of the Hanseatic League (*q.v.*) and its merchants had probably the widest connections and the most varied trade of all the German towns. Crafts included the making of textiles and books and working in leather, enamels and metals, the work of Cologne's goldsmiths being particularly fine. The wine industry was well established. The arts flourished and the city had many beautiful churches. The three greatest of the later scholastics, Albertus Magnus, Thomas Aquinas and Duns Scotus, all taught in its schools. After the Thirty Years' War, however, the city declined, partly, no doubt, as a result of the exclusion of Protestants and Jews. As late as 1794, when the French occupied the city, public Protestant services were banned, and the city remained predominantly Roman Catholic in the 20th century. The Jewish community, which had existed in the time of Constantine, was expelled in 1424 and until 1794 no Jew was allowed to stay overnight in the city.

In 1801 Cologne was taken by France and when the archbishop elector died a year later the see was left vacant. The archbishopric was restored in 1821. In 1815 Cologne passed to Prussia and from that time a new era of prosperity began. Its industry showed as wide a variety as in medieval days, and when railways were introduced its geographical position made it a great railway centre. The interest in organization, shown in the days of the guilds, contributed in the early 19th century to the formation of a chamber of commerce, the oldest of its kind in western Europe. The population grew from 41,685 in 1801 to 372,529 in 1900 and 768,352 in 1939.

In World War II Cologne suffered 262 air raids; there were 20,000 casualties and the city was left in ruins, with nearly all the dwellings in the old town damaged and 91 out of 150 churches destroyed. In April 1945 the population had sunk to 69,000. By December, however, there were 447,000 in the city and the population continued to rise rapidly, while a vast work of clearance and reconstruction was undertaken.

See also references under "Cologne" in the Index.

For full account and detailed bibliographies see E. Keyser, *Rheinisches Städtebuch* (1956). (M. KL.)

**COLOMB, PHILIP HOWARD** (1831-1899), British naval officer and historian, born in Scotland on May 29, 1831, was an innovator of tactics for steam warships and the inventor of an improved system of signals. He entered the navy in 1846, serving successively in the Mediterranean, China, Burma, the arctic and in the Crimean War, when he took part in the bombardment of Sveaborg. Among his later services was the suppression of the Arab slave trade when in command of the "Dryad" (1868-70), of which he left an account in his *Slave Catching in the Indian Ocean* (1873). His new system of signals was adopted in 1867, and his recommendations on the causes of collision at sea were adopted at an international conference in 1889, three years after his retirement from the navy. Colomb made a special study of naval tactics for steam vessels, and his biography of his friend Adm. Sir Astley Cooper Key is a valuable contribution to the history of that epoch of changing methods of sea warfare. In his *Naval Warfare* (1891) he came independently to many of the conclusions about the new meaning of sea power that later were publicized by Adm. Alfred Mahan. He died at Botley, Hampshire, on Oct. 13, 1899.

His younger brother, **SIR JOHN COLOMB** (1838-1909), an officer in the royal marines and a member of parliament, was also the author of a number of works on sea warfare and imperial defense, among which may be noted *The Defence of Great and Greater Britain* (1879), *The Use of Marine Forces* (1883) and *Imperial Federation: Naval and Military* (1886). (C. C. L.)

**COLOMBE, MICHEL** (c. 1430-c. 1512), an important (and also the last) Gothic sculptor in France, was born in Brittany (bishopric of St. Pol de Leon). Nothing is known about his early

life and works, but by 1473 he had set up shop in Tours. His generally acknowledged masterpiece is the white tomb of Francis II of Brittany and his consort Marguerite de Foix (1502-07) in the cathedral of Nantes. The four corner figures of Virtues are particularly to be remarked. The only other certain work of Colombe is the marble panel of St. George and the Dragon (in the Louvre), commissioned by Cardinal d'Amboise for the chapel of his palace at Gaillon near Rouen. Italian influence on Colombe's work is very slight, and that only in details. He died in Tours after 1512.

See Paul Vitry, *Michel Colombe et la sculpture française de son temps*, with full bibliography (1901). (A. K. McC.)

**COLOMBES**, a suburb of Paris, Seine département, is situated on the left bank of the Seine in the Gennevilliers loop of the river, 13 km. (8 mi.) N.W. of Notre Dame cathedral by road. Pop. (1962) 76,849. Colombes is a working-class district and 15,000 of its inhabitants are employed in local factories making pneumatic and electrical equipment, measuring instruments, copper and sheet-metal work, cycles and motor scooters, plastics, ceramics, oil and vinegar. Colombes is on one of the suburban railways from St. Lazare station, Paris. The largest stadium in the Paris district was built there on the site of the old racecourse. (H. DE S.-R.)

**COLOMBIA** (REPÚBLICA DE COLOMBIA) is a republic occupying the northwestern angle of South America. It is bounded on the north by the Caribbean Sea and Venezuela; on the east by Venezuela and Brazil; on the south by Brazil, Peru, and Ecuador; and on the west by Ecuador, the Pacific Ocean, Panama, and the Caribbean Sea. The republic has an extreme length from north to south of 1,050 mi. and an extreme width of 860 mi. It has an area of 439,735 sq.mi. and a population (1964) of 17,484,508.

## I. PHYSICAL GEOGRAPHY

**1. Geology.**—The Andes reach their northern end in Colombia, where they are divided into three principal ranges, of which the central one is the highest. This range, the Cordillera Central, which is separated from the western one by the valley of the Cauca and from the eastern one by the valley of the Magdalena, includes peaks rising to heights of approximately 18,000 ft. The highest of these, Nevado del Tolima (17,109 ft.), Nevado del Huila (18,701 ft.), and Nevado del Ruiz (18,340 ft.), are volcanic.

The western chain, the Cordillera Occidental extends northward from Ecuador nearly to the Caribbean Sea. In its southern part it is flanked by steeply tilted Paleozoic beds and by Mesozoic beds. The eastern Andean range is composed mainly of folded Cretaceous beds. The Cordillera Central consists chiefly of beds of Cretaceous sandstone and porphyritic rocks. The axes of folding in all these ranges conform in direction with the trend of the ranges. Along the Pacific coast of Colombia there is a lower range, composed mainly of volcanic rocks, which are covered in places with soft Quaternary sandstones and marls. The Magdalena Valley is a structural trough 560 mi. long and 9–56 mi. wide. The Cúcuta Basin, which is a southwestward continuation of the Maracaibo Basin of Venezuela, is occupied by Cretaceous and Tertiary formations. In the part of Colombia that lies east and southeast of the Andes the surface deposits are mainly Tertiary and Quaternary sand, loam, and gravel.

**2. Physiography.**—The western and northwestern sections of Colombia are occupied by the terminal ranges of the great Andean system. The two closely parallel ranges of northern Ecuador unite to form the Macizo de Pasto as they enter southern Colombia.

From this great mountain knot, in turn, the Western and Central cordilleras of the triple-spurred Colombian Andes emerge and stretch away side by side toward the north. The Eastern Cordillera originates in a secondary knot in the central range not far north of the Macizo de Pasto, and crosses the country in a northeasterly direction until it in turn splits asunder, sending one spur north into the Caribbean to form the Guajira Peninsula, and the other to the east to form the Sierra Nevada de Mérida south of Lake Maracaibo in western Venezuela.

The Eastern Cordillera sharply divides the mountainous district of northern and western Colombia from the low-lying plains of the interior which comprise slightly more than half the total area. To the south, a region covered by nearly impenetrable jungle growth is drained by the tributaries of the Amazon. Except along the principal rivers it is largely unexplored and inhabited mostly by uncivilized tribes of Indians. The northern part of these transmontane lowlands, the llanos, is a region of open tropical plains, alternately flooded and parched with the changing seasons and drained by tributaries of the Orinoco. The approximate length of this region is 640 mi. and the average width 320 mi.

The Western Cordillera roughly follows the line of the Pacific coast, terminating in three low, wooded spurs which merge into the Caribbean coastal plain in the southern part of Bolívar and Córdoba. A short transverse range connects it with the Cordillera de Baudó, which extends from the mouth of the San Juan River north to form the highlands of Panama. The Western Cordillera is covered with vegetation, and its Pacific slopes are precipitous and humid. Its highest elevation, the Nevado de Cúmbal, is 16,043 ft. and stands

near the Ecuador border. To the north, the range is lower, with summits of 13,300 ft. A low saddle between the Cauca Valley city of Cali and Buenaventura, on the Pacific coast, is an important transport route.

The Central Cordillera, also called the Quindío, is separated from the eastern and western Andean ranges by the Magdalena River on one side and its principal tributary, the Cauca, on the other. It terminates in low hills near the confluence of the two rivers.

The Central Cordillera has a series of lofty volcanoes, some of them perpetually snowcapped. Its highest elevation is the Nevado del Huila. The cordillera is crossed at an elevation of 11,434 ft. by the Quindío road, historically the main route followed by travelers between Bogotá and the Cauca Valley and Buenaventura. The northernmost extension of this range is the granitic batholith of Antioquia, an old peneplained upland surface (average elevation, 7,000 ft.) which is shot through with gold-bearing veins. It supported the most important mining activity in colonial New Granada.

The Eastern Cordillera is the region of densest population and is distinguished by its large area of plateau and elevated valley lying within the limits of the vertical temperate zone. The *sabana* of Bogotá (8,660 ft.), with an area of 425 sq.mi., is a good illustration of the higher of these plateaus. Sogamoso lies in another. Mild in temperature and fertile, they have the varied production of the temperate zone. They are the beds of former Pleistocene lakes, some of them interconnected, that have dried up with the diminution in precipitation at these latitudes. From

Bogotá or Sogamoso one may drop abruptly to the edge of the eastern llanos by road in a few hours.

The Pacific coastline, omitting minor convolutions, is about 800 mi. in length; that of the Caribbean is about 1,000 mi. The Caribbean ports are Barranquilla, Cartagena, Santa Marta, and Ríoacha. There are two commercial ports on the Pacific coast, Buenaventura and Tumaco. Because of its unhealthy character and the high mountain barriers, the Pacific coast has played only a slight role in the country's development. The Caribbean plain is hot and low except in the northwestern section of Magdalena Department, where the surface is elevated in the Sierra Nevada de Santa Marta whose lofty, snow-covered peaks reach 18,693 ft.

The Caribbean islands of San Andrés and Providencia, 300 mi. N of the South American mainland and 120 mi. E of the Central American shore, lie within Colombian jurisdiction, as does Malpelo Island off the Pacific coast.

**Rivers.**—For convenience of description the rivers may be divided into three general classes: those that find outlet in the Pacific, those that flow into the Caribbean, and those whose waters reach the Atlantic through the Orinoco and the Amazon. The most important rivers in Colombia are the Magdalena and its principal tributary the Cauca (*see* MAGDALENA RIVER; CAUCA RIVER). Both rise in the high plateau of the Andes adjoining Ecuador. The Magdalena empties into the Caribbean Sea near Barranquilla. It is about 950 mi. long and traverses nearly the entire country. In the lower reaches, throughout perhaps half its course, the waters of the Magdalena are dissipated over a wide area of swamp, lagoons, and lakes, and its course is continually changing through the wearing away of its alluvial banks. The Cauca unites with the Magdalena about 200 mi. from the sea through several channels. The Cauca is navigable in two widely separated stretches of 200 mi. each. The upper section, between Cali and Cartago, is no longer much used but there is still a considerable traffic on the lower river downstream from Cáceres. The lower Cauca and its right-bank tributary, the Río Nechí, have built up extensive deposits of gold-bearing gravels, especially in the vicinity of Pato and Zaragoza in Antioquia. These gravels were being dredged by U.S. and Canadian mining interests as early as 1909. Both the Río Atrato (*q.v.*) and Río Sinú flow to the north coast and are navigable by small steamers.

The rivers of the Pacific coast are numerous. They have short, precipitous courses with comparatively short navigable channels. From the downstream section of the Río Atrato the low passes to the west along the routes of the Río Truandó or the Río Salagüí provide easy access to the Pacific coast and have been suggested as possible routes for a second interoceanic canal.

The waters of the rivers of the great eastern plains pass to the Atlantic through the Orinoco and Amazon rivers. Some of them are navigable, which fact may be of great importance to the future development of this region, as yet only partially explored.

**3. Climate.**—Colombia lies almost entirely in the north tropical zone. The heat of the tropics is, however, modified throughout a large part of the area by the elevation of the surface and the action of winds. In general, high temperatures prevail in the lower areas, including the coastal plains and the valleys of the larger rivers. These regions are characterized by excessive moisture and dense forests, except where agricultural colonization has been active. The health conditions in these lowlands have recently been much improved, especially by means of the successful campaigns against malaria. Above the tropical zone in the mountainous area are found all gradations of cooler climate. The subtropical districts comprise the valleys and slopes lying between 1,500 and 6,000 ft. of elevation. Some of them are among the most fertile and productive areas of the country. The temperate zone lies between 6,000 and 10,000 ft., and the cold, bleak paramos are from 10,000 to 15,000. Above these are wastes of ice and snow. Most of the principal cities are situated between 3,000 and 9,000 ft. above sea level in areas of temperate climate.

In general, the year is divided into a wet season called *invierno*, or winter, and a dry season called *verano*, or summer. In some sections there are two wet and two dry seasons. The time when these seasons occur and their duration vary greatly, however, in

the different regions and even vary from year to year in the same location. The driest area of Colombia is probably the northernmost part of the Guajira Peninsula where the average annual rainfall is less than ten inches. Humidity, however, is relatively high. There are local pockets of aridity in the upper parts of the valleys of the Cauca and Magdalena rivers as, for example, the Dagua Valley on the Cali-Buenaventura route and the Neiva area in Huila. The rainiest area in Colombia, and probably in all of South America, is the Pacific coastal zone, especially near the San Juan-Atrato divide in the department of Chocó. There, average annual rainfall exceeds 400 in. (Andagoya, 415 in.) and there is no dry season.

**4. Vegetation.**—The Colombian vegetation is very rich, ranging as it does through all varieties from those of the tropics to the alpine species of the highest plateaus. A luxuriant forest growth covers a large part of the republic, including the foothills, slopes, and valleys of the cordilleras; a large part of the plains adjacent to the north coast; the entire surface of the Western Cordillera and coast; and the southern section of the eastern plains. There are many varieties of forest products, including vanilla and medicinal plants such as quinine, ipecac, sarsaparilla, gums, and balsams, also rubber, tanning agents and dyewoods, and the tagua nut, known as vegetable ivory. Forest products form a potential source of wealth as yet little exploited. Up to an altitude of 10,000 ft. the palm is abundant and varied, with incredibly numerous uses. There are extensive groves of the coconut palm on the Caribbean coast. Orchids are abundant in the forests and many valuable varieties have been secured in Colombia. The great stands of *guadua* or American bamboo, especially in the Valle del Cauca, provide a widely used construction material. Human activity in recent years has been converting vast tracts of the tropical lowlands, especially on the north coast, to artificial pastures, dominated by guinea grass, Para grass, and jaragua.

As the surface of the land rises the character of the vegetation changes. From 1,500 to 4,500 ft. there is a great variety of semi-tropical fruits. The temperate zone commences at 6,000 ft. and is a dairy and agricultural region. There practically all the cereals, vegetables, and fruits commonly found in the United States are produced. Above 10,000 ft. are the paramos with stunted vegetation. Farther up only alpine species are found. Colombia is especially rich in fine woods. The varieties include mahogany, lignum vitae, brazilwood, walnut, cedar, oak, and many others. One of the most useful trees of the temperate zone is the eucalyptus introduced from Australia. Extensive areas have been planted to leguminous trees to provide shade for coffee plants.

**5. Animal Life.**—The fauna of Colombia reflects in its composition the climatic variety within the country, from tropical lowland to the icy paramos of the high mountains; the isolation of the valleys by the three great ranges of the Andes; and the position of the country at the meeting of the two American continents. The rich, tropical Amazonian forest fauna ranges into Colombia from the south in the drainages of the Amazon and Orinoco. This group includes sloths, anteaters, opossums, and a variety of monkeys. The larger herbivores are the tapir, the two kinds of peccary, and various deer, as well as large tropical rodents such as the paca and the agouti. The carnivores are the puma and jaguar, a variety of smaller cats, foxlike canids, raccoons, and mustelids. The spectacled bear is almost entirely herbivorous.

Characteristically South American types of birds, such as toucans and hummingbirds, abound. More than 1,500 species and subspecies of birds are recorded. These include the many North American migratory forms that winter in Colombia. Reptile life is likewise rich, with a great variety of turtles, lizards, and snakes. The widespread American crocodile (which reaches the West Indies and the southern tip of Florida) is abundant in the Magdalena River. There are various smaller species of caymans. Among amphibians there are a few caecilians, a few species of salamander, and a multitude of frogs. The freshwater fishes are of South American types, including catfishes and characins in abundance, and also the electric eel and related forms.

The insect fauna of the country as a whole is extremely rich and far from being fully known. During and after World War II

southern Colombia was a centre for the intensive study of mosquitoes, a necessary part of the campaign against malaria and jungle yellow fever. (Js. J. P.)

## II. GEOGRAPHICAL REGIONS

The exaggerated physical contrasts within Colombia and the relative difficulty of east-west movement have tended to compartmentalize economic and political life and to intensify regional distinctions. Unlike most Latin-American countries, Colombia has no single preeminent metropolis, but rather a series of regional capitals that are comparable in size and economic importance. The Andean or interior orientation of the economy has persisted since pre-Columbian times.

**1. Caribbean Coastal Lowlands.**—These comprise an extensive zone of low, rolling hills, marine terraces, and river alluvium lying between the northern Andes and the sea. Despite its early colonial importance (Santa Marta and Cartagena were the first permanent cities in Colombia), this coast has been an area of cultural lag. It supports about 17% of the population, most of whom live in the urban centres of Barranquilla, Cartagena, and Santa Marta. The low, forested spurs (Sierra de Abibe) of the Western Cordillera reach the coast between the Gulf of Urabá and the Sinú River. To the west lie the rain-drenched and nearly uninhabited lower Atrato River plains. To the east, in the Magdalena plains, the lowland zone widens to more than 200 mi. The granite Sierra Nevada de Santa Marta, which rises behind the port of Santa Marta, is probably to be thought of as an outlying peak of the Eastern Cordillera system. Beyond it, to the northeast, the low hills of the arid Guajira Peninsula extend in the shape of a closed fist, the northerly projection of the Sierra de Perijá, which forms the frontier with Venezuela.

The rivers of the coast are sluggish, meandering streams bordered by extensive areas of seasonally inundated swamps (*ciénagas*). The bordering *ciénagas* of the Magdalena and the Sinú provide pasturage and drinking water for livestock during the *verano* (January to May) when the upland grasses are seared with drought. The rich riverine alluvial soils are but little cultivated because of the difficulty of flood control and the unreliability of the rainfall. The Magdalena floodplain is of relatively restricted extent near the coast, where it is hemmed in on the west by the Tertiary hills of Atlántico, but upriver from Magangué it is joined by the San Jorge, the César, and the Cauca rivers in a vast area of ill-drained seasonal swamps and lakes. The Sinú, navigable for small vessels inland to Montería, also has extensive bordering swamps, of which the Ciénaga Betancí and Ciénaga Grande are of the greatest extent.

The climate of the coast is warm and relatively dry. Aridity increases from west to east, in part because of the northerly trend of the coast which carries the Guajira into the subtropical trade-wind zone at latitude 12° N. The annual average precipitation, 45 in. in the lower Sinú, is 25 in. at Cartagena and less than 10 in. in the Guajira. Inland, however, the dry season becomes everywhere less pronounced and total precipitation increases sharply. Near the confluence of the Cauca and Magdalena it exceeds 120 in. and supports luxuriant rain-forest vegetation.

Stock raising has been the traditional economic activity of the coast. Successful large-scale agricultural developments, with

cotton and sesame as the principal crops, have taken place on the better-drained alluvial lands in the Sinú and César valleys. The extensive irrigated acreage in bananas in the lee of the Sierra Nevada de Santa Marta, and smallholder mixed farming on the hills between Barranquilla and Cartagena date back to an earlier period. At Turbo, on the Gulf of Urabá, bananas have become a major crop.

**2. Pacific Lowlands.**—These comprise the narrow, rain-drenched littoral between the Western Cordillera and the Pacific Ocean. By convention, they may include the physically and culturally similar Atrato River drainage, though the Atrato empties into the Caribbean. The Pacific lowlands thus comprise the department of Chocó and the forested, empty Pacific slopes of the departments of Valle del Cauca, Cauca, and Nariño. Because of the excessively high rainfall, generally more than 200 in. a year, this entire area is cloaked in a lush rain forest. Its deeply weathered red lateritic soils offer very limited agricultural promise. Rivers are the principal highways of communication and agricultural clearings and settlements are largely confined to their natural levees. The Pacific lowlands are scantily peopled. About 85% of the area's 335,000 population is of Negroid stock, descendants of escaped slaves who worked the gold and platinum placers during the colonial period. A proposal for the construction of an inter-oceanic canal in this area was made in 1540. It was still under consideration at mid-20th century.

**3. Eastern Plains (the Oriente).**—Although they comprise two-thirds of the area of Colombia, the eastern plains contain less than 2% of the country's population. They are the vast outwash surfaces and fans of the numerous streams that drain the eastern face of the Andes, among them the Arauca, the Casanare, the Meta, the Caquetá, and the Putumayo. In the past, malaria, banditry, and isolation have tended to retard their economic development. In the northern third of the region, which lies within the Orinoco drainage, the dry season is well marked, soils are better, and there are extensive areas of open savanna (*llanos*) which have long been exploited by stockmen. South of Villavicencio, within the Amazon drainage system, the savanna openings become less frequent. The vast *comisarias* of Vaupés and Amazonas and the *intendencias* of Caquetá and Meta are almost entirely cloaked with dense rain forest (*selva*), inhabited almost exclusively by primitive Indian groups. Colonization zones, however, have been established along roads of penetration from the Andean foothills, as at Florencia and Mocoa.

VALLEY OF THE RÍO NEGRO, EASTERN COLOMBIA

**4. Andean Region.**—This area, whose temperate climate, mineral wealth, and large Indian population originally exerted so strong an attraction on the Spaniards, still is the centre of political and economic power in Colombia. There live 78% of the population and there are the three largest cities—Bogotá (pop. [1964] 1,661,935), Medellín (717,865), and Cali (618,215). The Andean region may be broken down into numerous subregions or economic-physical areas, each with distinctive characteristics. The massive Eastern Cordillera has been the traditional centre of Chibcha, Spanish, and Colombian culture and government. The most dense rural settlement and largest cities are generally on the higher plateaus and interior basins of the *tierra fría* (e.g., Bogotá, Chiquinquirá, Sogamoso, Tunja). To the north, in the Santander, elevations are lower and sugar, cotton, tobacco, and coffee replace potatoes, wheat, and barley as the primary crops. Deep barrancas such as that of the Río Sogamoso cut into the flank of the cordillera and make north-south travel difficult except along the flattened Andean crest, but movement between the highlands and the Magdalena Valley is relatively easy. The peoples of the Eastern Cordillera are mostly ultraconservative subsistence farmers living on dispersed farmsteads. Extreme poverty and excessive parcelization of the land are found in this area. In some places, near the larger cities, dairying and truck farming have prospered. Tobacco is an important crop in Santander, as is coffee on the mid-slopes toward the Magdalena below 6,000 ft. elevation.

The middle and upper Magdalena Valley, a deep, grabenlike depression, stands apart as another distinctive land. Life on the windswept open plains of Tolima and Huila, where water is at a premium much of the year, contrasts sharply with that of the cordilleran slopes that rise abruptly on either side. Commercial agriculture (tobacco, cotton, sesame, artificial pasture) has become important, especially in Tolima, where irrigation waters are taken from streams such as the Coello as they flow eastward across a wide alluvial apron before joining the Magdalena.

The central and western Andean cordilleras are distinguished from the eastern highlands by their steep slopes, often of volcanic origin, and by the distinctive qualities of their people. In the far south the volcanic outwash slopes coalesce to form high intermontane valleys and plateaus with relatively flat surfaces, as at Ipiales, Pasto, and Popayán. There, and especially in Nariño, the rural population is dense and Indian ways survive. Northward from the Popayán district, commercial agriculture and the production of cash crops for sale become more important and cities become more numerous. The Valle del Cauca, the 120-mi.-long, flat-floored valley 3,000 ft. above sea level, is the floor of a former lake that was probably formed when the Cauca River was dammed by Pleistocene volcanic eruptions to the north. It is a clearly delimited physical and cultural subregion, centring on the flourishing commercial city of Cali (q.v.), headquarters for the Cauca Valley Development project, which was modeled after the Tennessee Valley Authority. The floor of the valley, alternately subject to flooding and drought, has been traditionally devoted to the raising of pasture grasses, sugarcane, tobacco, and rice. The mountains overlooking the valley on either side were colonized by Antioqueño settlers, the front wave of aggressive frontiersmen who began moving south onto the unpeopled mountainsides overlooking the Cauca gorge in southern Antioquia during the 19th century. These small Antioqueño farms, together with those in Caldas and western Tolima, produce the bulk of Colombia's exportable coffee. The department of Caldas, carved from the three states of Tolima, Cauca, and Antioquia in 1905 by Antioqueño homesteaders, produces one-third of the country's coffee crop though the roughness of the topography makes local farm-to-market roads impractical. An exception is in the rich Quindío district of southern Caldas where gentler slopes prevail.

The Antioquia granite batholith, the terminal rampart of the Central Cordillera, is a relatively flat surface of limited agricultural attraction, but the lower volcanic slopes to the south and west and the folded Tertiary ranges of the Western Cordillera beyond the Cauca trench are of superior productivity and soil erosion there has been contained. After 1800 these slopes were centres of intensive colonization and agricultural development as

BY COURTESY OF STANDARD OIL CO. (N.J.)

WORKERS SPREADING COCOA BEANS TO DRY AT A PLANTATION IN THE CAUCA RIVER VALLEY

the surge of colonists southward from the Antioqueño core area around Medellín and Rionegro got under way. Medellín remains the regional capital and cultural heart of this northern highland zone, its original importance as a mining centre having later been overshadowed by trade and industry.

### III. THE PEOPLE

**1. Physical Types and Languages.**—Colombia is a mestizo country where the mixing of Indians and whites has been going on for four centuries. Persons of unmixed European descent may constitute 10–15% of the total population; they are represented chiefly by the upper classes of the larger cities and by a part of the rural population of Antioquia, Caldas, and the Santander. An estimated 20% of the population is Negro or mulatto (see *Population*, below). The 1951 census recorded approximately 300,000 Indians, including the tropical forest tribes of Amazonas, the desert Guajiro, and the Páez of the Tierradentro country near the headwaters of the Magdalena River.

The Indian population of pre-Columbian New Granada was both numerous and culturally advanced (see *History*, below). The Tairona, Sinú, Quimbaya, and Chibcha and their relatives, while lacking the political sophistication of the Incas and Aztecs, were peoples of high culture for whom manioc (cassava), potatoes, and maize were the principal staples. The assimilation of colonial Spanish culture by aboriginal tribes was curiously rapid and complete. This was favoured by the fact that most of the tribes were small in number and scattered, speaking different languages. In much of the land west of the Magdalena the Indian population seems to have been virtually exterminated within a few years of the first *entradas* by wars, epidemics, or forced exile. In the Eastern Cordillera and in Nariño the Indians survived in the largest numbers, usually on land reserves (*resguardos*) which had been first established by Spanish legislation at the end of the 16th century. Even there, however, the Spanish language was adopted, together with European dress and the Roman Catholic religion. It is in the southern highlands of Nariño and in the highlands of Boyacá and Cundinamarca in the Eastern Cordillera that the Indian element is most conspicuous in the rural mestizo population. On the Caribbean coast and in the Cauca Valley, especially, Negroes have intermingled with whites and Indians to form an ethnic stock of distinctive character. Wherever slave labour was employed extensively during the colonial period, as in the Antioquia mining camps, the Negro element is often still substantial. The principal Negro area of Colombia, however, is the Pacific coastal lowland. The tiny Colombian-owned islands of San Andrés and Providencia have a predominantly Negro population of Jamaican ancestry.

The modern Colombian is not cut to any single mold. Perhaps because of the country's extreme physical diversity, cultural particularism is highly developed in the various departments and regions. Antioqueños, Santandereños, Tolimense, Nariñense,

Bogotanos, and Boyacense are recognized by habits of speech, dress, and diet at home and abroad.

Most numerous and economically the most important of these groups are the Antioqueños, self-styled "Yankees of South America," who in the 19th century spilled out from the heartland of Antioquia to colonize southward along the flanks of the Central and Western cordilleras. This energetic and cohesive cultural group, long renowned for its high birthrate and colonizing genius, numbers more than 3,000,000 persons, or close to one-fourth of the population. It has been one of the most important forces behind the economic growth of the country during the 20th century. Wherever he has gone, the Antioqueño has transplanted his unique cultural heritage. Caldas has become a department "more Antioqueño than Antioquia." Antioqueño smallholders produce three-fourths of Colombia's coffee and control much of the country's trade, banking, and manufacturing. The popular belief that Antioquia was settled in part by Sephardic Jews recently converted to Christianity has never been substantiated. Among the other principal cultural groups of Colombia the Santandereños—physically, at least—most resemble the Antioqueños. They are a mountain folk of predominantly white stock. Bucaramanga is their principal urban centre. European immigration has been of relatively little importance in Colombia since the colonial period.

**2. Religion.**—The Roman Catholic faith was introduced into Colombia by the Spanish conquerors and until 1853 was the only religion permitted to Colombians. Until amended in 1936, the constitution provided that Roman Catholicism should be the national religion protected by the state, but a complete disestablishment was effected in that year. During the colonial period many churches were built and religious communities established, and the church was wealthy and powerful. Although under Pres. Tomás Cipriano de Mosquera (*q.v.*) most of the church property was transferred in 1861 to the state, the church remained quite strong. Its influence in matters of education was materially decreased by the policies followed under Pres. Alfonso López Pumarejo (1934–38). However, the Catholic Church is probably stronger in Colombia than in any other country in South America. Other forms of religion are permitted as long as they are "not contrary to Christian morals and to the law." Protestant missionary activities have not been lacking, but in 1953–57, during the internal strife associated with the rule of the dictator Gen. Gustavo Rojas Pinilla, Protestants complained of police persecution and religious disorders. Terrorism against Protestants has been openly condemned by the government and the Vatican.

**3. Customs and Culture.**—Isolation has tended to preserve the language, manners, and physical characteristics of the early colonists with less variation in Colombia than in any other Spanish American country. The traditional cultural ties of the upper classes have been with Europe, but during and after World War II the United States came to be of primary importance in this regard. Bogotá, "the Athens of South America," has always prided itself on being a centre of learning, with special emphasis on literature, poetry, and music. The writing and reading of poetry traditionally has had an especially important place in the Colombian hierarchy of values although few Colombian poets are known beyond the limits of their country. Regional literature has been developed to an extraordinary degree and reflects a keen appreciation of local history and geography. The study of anthropology developed notably during and after World War II, particularly at the Instituto de Antropología in Bogotá.

The conservative quality of Colombian life is a matter of frequent comment by visitors. The *ruana* or poncho cloak is everywhere worn by the country people. Among those with a more Indian culture the felt derby hat is worn by both sexes. In the cities, men in traditional black hats and suits still crowd the streets during the evening hours for long political debates over their *tinto*, or coffee demitasse. Women's life is traditionally centred in the home. Courting is still carried on through the iron grills that frame the street windows of private houses.

See also INDIAN, LATIN-AMERICAN; SOUTH AMERICA: *Anthropology*; ARAWAK; CARIB; CHIBCHA. For Colombia's literary development see IBERO-AMERICAN LITERATURE. (Js. J. P.)

#### IV. HISTORY

**1. Preconquest.**—Even before the Spanish conquest the western mountainous part of Colombia attracted the bulk of the population. The higher Indian cultures were found in this region, and the most favourable location for the growth of civilization was the high plateau in the Eastern Cordillera of the Colombian Andes. The present capital city of Bogotá is located near the southern terminus of the plateau, which extends northward to the mountains dividing it from the drainage of the Río César. There the Spanish found the major concentration of the Chibchan-speaking peoples. (See CHIBCHA.) At the time of the Spanish conquest the Chibcha were in the process of consolidation by warfare. They had not achieved firm union and political institutions, and their other cultural traits had not attained the solidity and refinement needed to resist cultural conquest.

Except for the invading Carib peoples in the deep mountain valleys, there was a considerable similarity among the Chibcha, subandean, and circum-Caribbean cultures of Colombia. They were all characterized by intensive agriculture, fairly dense populations, living in villages, organized religion, class divisions, and matrilineal inheritance of political and religious offices. The subandean culture in the Central Cordillera and the narrower portions of the Cauca Valley generally lacked the feature of large villages because of the unsuitability of the terrain. The more advanced Chibcha made war for political ends, using large forces armed with the dart and dart thrower, shields, and wooden clubs.

Geographic and climatic conditions placed limits to the development of the Chibcha and other cultures in Colombia. Of the total Indian population at the time of the conquest, probably about one-third were Chibcha. None of the larger domesticated animals and their wild related species found in the central Andes existed in Colombia, where only the dog and the guinea pig were domesticated. The Chibcha were adequate craftsmen, but their work shows more interest in utility or in the expression of ideas than in the attainment of the skilled workmanship striven for among the subandean peoples such as the Quimbaya of the Cauca Valley. No significant use of stone in construction was made and the famed stone ruins at San Agustín in the upper Magdalena Valley date from a much earlier period.

**2. Conquest.**—Exploration of the Colombian coastline was the work of Rodrigo de Bastidas, who in 1500–01 ran out the Caribbean coast from Cabo de la Vela to Nombre de Dios in Panama, and of Francisco Pizarro, who sailed the Pacific coast in 1525. Effective conquest of Colombia began in 1525 with the founding of Santa Marta on the north coast by De Bastidas. In 1533 Pedro de Heredia founded Cartagena, which became one of the major naval and merchant marine bases of the empire. By the end of 1539 all but one of the major inland colonial cities had been founded, as well as the most important communications centres along the routes connecting them. The capital city of Santa Fe de Bogotá was founded by Gonzalo Jiménez de Quesada in 1538. By 1550 the era of the conqueror drew to an end.

**3. Colonial Era.**—Establishment of the *audiencia* of Santa Fe de Bogotá in 1550 opened the colonial era. The conquerors had organized local governments in accordance with the terms of their contracts with the crown. The crown then rapidly repossessed the broad powers granted the conquerors and formed its own institutions to rule the empire. Popayán, Antioquia, Cartagena, Santa Marta, Ríoacha, the New Kingdom of Granada (Bogotá), and the llanos of Casanare and San Martín were made subject to the new *audiencia*. The president of the *audiencia* was the executive head of government, subject to the viceroy of Peru in administrative matters. The difficulties of travel, however, impeded communications and checked centralized control.

The area declined in population after the conquest as a result of disease and the economic demands made upon the Indians. As elsewhere in the empire, the downward trend seems to have reversed itself at the end of the 17th and the beginning of the 18th century. Acculturation and intermarriage rapidly destroyed most of the special cultural traits of many remaining Indians. Subordinate political jurisdictions developed strong regional characteristics as a result of isolation, which fostered intense local

BY COURTESY OF STANDARD OIL CO. (N.J.)

loyalties and rivalries. The economy was based on mining and agriculture but a small yet important textile industry had grown up in Socorro, north of Bogotá, by the mid-18th century. Slavery was introduced during the conquest and became common in the placer-mining areas of the Chocó and western Antioquia and in the agricultural regions of the Cauca Valley, the lower Magdalena Valley, and the coastal lowlands. Indians were subject to the *encomienda* tribute, but by 1700 most of the privately held *encomiendas* had reverted to the crown and they were rarely granted thereafter. During the era of the *audiencia*, from 1550 to 1740, the population was politically quiet. The Roman Catholic Church played a very important role in the life of the people, providing most of the welfare services and operating most of the schools. The church was an effective instrument of the crown, since the latter controlled appointments to church offices, intervened in church administration, and censored official church documents.

**4. Viceroyalty.**—Creation of the viceroyalty of New Granada, which included present-day Colombia, Venezuela, and Ecuador, temporarily in 1717–23 and permanently in 1740, opened a new era. In the next decades the crown introduced political and economic

measures to reorganize and strengthen the empire by greater centralization of authority, improved administration and communication, and freer development and movement of trade within the empire. These changes coincided with and were an effect of new, important trends in western Europe. Population grew, trade increased, and prosperity touched the colonial subjects. There was a spurt of intellectual activity and the formation of a corps of Creole intellectuals and professional men, many in government positions. (See CREOLE.) The Creole officer corps, small though it was, came into being when Charles III authorized militia defense units in the colonies. A relatively large group of wealthy landowners and merchants constituted the economic community that supported these new groups. Between 1785 and 1810 in New Granada the outlook of the Creole upper and middle groups changed from resistance toward political and economic change introduced by government to a quest for specific changes in imperial policies. Thus in the Comunero Rebellion of 1780–81 the Socorranos opposed change, while in 1809 they proposed new policies leading to the free-enterprise system, the abolition of slavery, restrictions on government, and worldwide freedom of trade. The intendency system (see INTENDANT) of administration was not established because of the Comunero Rebellion and later viceroys found it inexpedient to attempt it, although much of the terminology and some of the spirit of the system became a part of government.

Educational reforms played an important role in the changing outlook of the Granadines. Archbishop Caballero y Góngora as viceroy (1782–88) made education one of his main interests. He modernized the program of studies in the schools, opened a school of mines, and initiated the botanical expedition under the able guidance of naturalist José Celestino Mutis. The new institute greatly improved scientific education and trained many of the major figures of the independence movement. The 1790s were the decade in which the first newspaper and the theatre became features of Bogotá life. A new interest in writing developed and intellectual gatherings for discussion were introduced. In 1808 the allegiance of the Granadines to the crown remained unquestioned except for a few individuals. The once warm loyalty of the Creole middle and upper classes, however, was cooling under the pressure of economic interests, scandals in the royal family, and persistent social tension between Creole and European Spaniards.

The French invasion of Spain in 1808 caused an outburst of loyalty to king and country and excited grave concern for the church. Profound Granadine anxiety over the fate of the empire and conflicting courses of action attempted by colonial and peninsular subjects over control of government during the captivity of

Ferdinand VII led to strife in New Granada and to declarations of independence. In 1810 the subordinated jurisdictions in New Granada threw out their Spanish officials, except in Santa Marta, Ríoacha, modern Panama, and present-day Ecuador. The uprising in Bogotá on July 20, 1810, is commemorated as independence day in Colombia. These new governments swore allegiance to Ferdinand VII and did not begin to declare independence until 1811. To restore unity, all levels of government above the municipality had to be reconstituted by negotiation and agreement. Idealists and ambitious provincial leaders desired federation. Creole leaders who had been in Europe sought to centralize authority over the new governments. A series of civil wars ensued, facilitating Spanish reconquest of the United Provinces of New Granada between 1814 and 1816. A remnant of republican forces fled to the llanos of Casanare where they reorganized under Francisco de Paula Santander, who remained a prominent figure in Granadine politics until his death in 1840.

Any remaining loyalty to the crown was alienated by the punitive arbitrary conduct of the European and partisan troops whose officers ignored the Spanish civil authorities. Their conduct gave validity to the attack on Spanish civilization that began late in 1810 and continued throughout the 19th century. The forces in Casanare joined those of Simón Bolívar (*q.v.*) in the Orinoco Valley of Venezuela. By 1819 arrangements for a regular government were completed and a constitutional convention met at Angostura (now Ciudad Bolívar, Venez.) with delegates from Casanare and some Venezuelan provinces. In that same year Bolívar invaded New Granada and decisively defeated the Spanish forces on Aug. 7 at Boyacá. There followed the decisive battle of Carabobo, Venez., in 1821 and that of Pichincha, Ecuador, in 1822. Mopping-up operations were completed in 1823, while Bolívar led his forces on to Peru.

**5. The Republic.**—The congress at Angostura laid the foundation of the Republic of Colombia (1819–30), generally known as Gran Colombia because it included Colombia, Venezuela, and Ecuador. The republic was definitively organized by the congress of Cúcuta in 1821. Prior to that time the government was highly military and strongly centralized with direct executive power exercised by regional vice-presidents while President Bolívar was campaigning. Organized as a centralized representative government, the republic had Bolívar as president and Acting President Santander as vice-president. Gran Colombia had a brief, virile existence during the war. Subsequent civilian and military rivalry for public office and regional jealousies led in 1826 to a rebellion in Venezuela led by Gen. José Antonio Páez. President Bolívar returned from Peru to restore unity, but secured only the acknowledgment of his personal authority. As discontent spread it became clear that no group loved the republic enough to fight for its existence. By 1829 Bolívar had divided the land into four jurisdictions under Venezuelan generals possessing civil and military authority. Meanwhile the convention of Ocaña had failed to reorganize the republic, and the brief dictatorship of Bolívar (1828–30) had no better success. Bolívar then convoked the convention of 1830 which produced a constitution honoured only in New Granada (Colombia). During this convention Bolívar resigned and left for the northern coast where he died near Santa Marta on Dec. 17, 1830. By that time Venezuela and Ecuador had seceded from Gran Colombia.

New Granada, after several changes of title, assumed the name of the Republic of Colombia in 1836. The many changes of constitutions in the republic's early history were related to three basic problems of Colombian society: the proper organization and powers of national and local government in relation to the needs and aspirations of the people; the adjustment of church-state relations to the constitutional principles of liberal republican government; and the hostility between the Liberal and Conservative parties, whose delineation took place in the 1830s. The constitution of 1836, which was still in use during the latter half of the 20th century, provided for a centralized form of government with provision for local autonomy. It represented a Colombian consensus formed of traditional practice, both legal and *de facto*, profound regionalism, and strong national feeling. Prior to 1855

both major parties were moderately centralist, and had been giving greater recognition to the demand for local autonomy. Thus, the number of units of local government with an alcalde, a town council, and a court of first instance increased from fewer than 200 to about 816 between 1832 and 1853. The number subsequently declined and in the mid-20th century the number of alcaldes was scarcely greater than in 1853. The alcalde has always held executive and judicial functions, and has taken part in the legislative process as chairman of the town council. His powerful position in the locality is easily convertible to tyranny. Responsible for enforcement of national, departmental (province, state), and municipal laws and ordinances in his area, he may interpret them in his own interest. In the 19th century, municipal officials generally received no salary. Alcaldes and judges were full-time officials whose offices had to support them if they had no other income.

Beginning with the civil war of 1840–42, relations between the parties remained on a basis of hostility, sometimes active and always latent. Party hostility led to the division of the country into federally related states (party strongholds) between 1855 and June 1857, and resulted in laws that limited the national government to minor functions with no provision for interstate or state-national governmental relations. The constitution of 1858 creating the Granadine confederation restored a national government. Liberal denial of that constitution led to the "organized anarchy" of the 1863 document under Liberal governments. A segment of the Liberal Party under Rafael Núñez then sought constitutional reform, and had to ally with the Conservatives to do it. The constitution of 1886 was the result, and the Conservatives retained control of the government until 1930.

The Liberal and Conservative parties were loosely knit associations generally led by extremists representing little more than two separate bodies of defined opinion. In the locality, political bosses known as *gamonales*, later *caciques*, provided leadership and determined the conduct of government through the alcaldes. From the *gamonales* and the intellectuals came the provincial and national leaders of the parties. The parties have frequently split and reunited, and they have made common cause against any individual who threatened to become an authoritarian military ruler as in 1854, 1909, and 1957. The highly organized status of the parties after World War I was not proof against division. Both parties still represented a complete cross section of the population.

Church-state relations were a crucial point in interparty relations. Until about 1840 both parties supported retention of the old powers of the Spanish crown over the church, but the Conservatives favoured easing the controls. Thereafter they tried to use the church as a political weapon in return for a protected status. The Liberals adopted a Benthamist approach in which, under "separation" of church and state, the church is regulated and deprived of property and its clergy are elected and paid as government officials. A number of leading Liberals were actively hostile to organized religion, and the party, hampered by the church's hostility to the basic philosophy of Liberalism, sought to limit its influence. The extraordinary bitterness of party hostilities was largely a product of the struggle over religion and the associated problem, control of education. Under the leadership of President Mosquera the power of the church was reduced in 1861 and most of its property appropriated by the nation. The settlement of 1886 and the concordat of 1888 quieted these issues until 1936.

**6. The 20th Century.**—Civil war (1899–1902) opened the 20th century at a cost of about 100,000 lives and economic ruin for the country. The government, victorious over the Liberal rebellion, was then confronted by the secession of Panama. In 1878 a French company had been given a concession to construct a canal across the isthmus of Panama. Although much of the excavation was accomplished in the 1880s, the problems of disease in Panama and of graft in Paris wrecked the enterprise. Subsequent efforts to revive the work failed, despite the cooperation of the Colombian government in extending the concession. As a result of experience in the Spanish-American War, the United States decided to build a canal either in Nicaragua or in Panama. The

latter route was selected, the Colombian government liked the idea, and the French company hoped to recover some of its losses. Negotiations broke down between the two governments and, threatened by the loss of the canal, Panamanian leaders in concert with the French company organized a rebellion and declared the independence of Panama in 1903. Using the treaty of 1846 with Colombia, the United States prevented the landing of Colombian troops but ignored the clause in which it guaranteed Colombian sovereignty over Panama. The United States then recognized Panamanian independence, negotiated a canal treaty, and began construction. Subsequently, under the terms of the Thompson-Urrutia Treaty ratified by Colombia in 1921, the United States made reparations for the loss suffered by Colombia, including a \$25,000,000 payment. Colombia then recognized Panama's independence. (See PANAMA CANAL.)

Forty years of political peace followed the loss of Panama. The disrupting effects of World War I on the economy were followed by fiscal and banking reforms in 1922 and the entry of foreign investment capital. Inflation followed. Wages of urban and rural workers lagged far behind the rising cost of living, and serious rural social disturbances occurred in several sections from 1925 to 1929. In the cities, modern labour organizations of a class character began to replace the old mutual associations. Division in the Conservative Party and popular unrest enabled the election of a moderate Liberal to the presidency in 1930. The new Liberal era lasted until 1946. Under the goad of the traditional spoils system and local vengeance, the harassed Conservatives were on the point of return to violence in 1932 when a conflict with Peru (1932-34) ended the internal struggle.

Pres. Enrique Olaya Herrera (1930-34) took initial steps to reform public health and education, public housing, and land distribution. A moratorium on debts was declared to counter effects of the depression. Pres. Alfonso López Pumarejo (1934-38) hastened the pace of reform. Labour enjoyed the patronage of government and the National Confederation of Workers became an important arm of the Liberal Party. Taxes on capital and income were effectively collected, an ineffective agrarian reform law was passed, and the government took on the philosophy of a welfare state. The social functions of property were established in law; public assistance was declared a function of the state; and the protected status of the church was terminated along with its control of education. Eduardo Santos Montejo, who succeeded López, did little more than maintain the work of his predecessor. During his second administration (1942-45) López was crushed between the opposition of his party's right wing to further reform and the necessities of the working class who looked to him to ease the impact of inflation and improve their standard of living. To this was added the pressure of an ever larger propaganda attack by the Conservatives as unrest grew among the people. López was driven to resign in July 1945, and Alberto Lleras Camargo filled his post until Aug. 7, 1946. In the 1946 elections the Liberals were so deeply divided that they ran two candidates: Jorge Eliécer Gaitán, who had made himself the leader of the working classes with a social reform program, and Gabriel Turbay, the candidate of the right wing. Moderate Conservative Mariano Ospina Pérez won the election, but his party did not win control of the congress until he imposed a state of siege on the country in 1949. This state of siege was partially lifted in 1958.

Ospina attempted until 1948 to govern with a coalition cabinet, hoping to restore peace and order to the country. Meanwhile his party began to move into the offices of government under the spoils system. Early in 1948 Gaitán was recognized as the leader of the Liberals only to be assassinated in Bogotá on April 9. The capital exploded into the worst riot in Colombian history and similar, less serious incidents occurred in other cities. The country had gradually moved into full-scale violence during the 1940s, a condition caused by interparty hatreds and social unrest. It was serious enough by 1944 to warrant extending the jurisdiction of military courts over certain crimes by civilians in areas where violence erupted. By August 1957 an estimated 260,000 persons had been killed and 750,000 had become refugees.

Laureano Gómez, extremist head of the Conservative Party, be-

came president in August 1950 and proceeded to eliminate Liberals from government payrolls. By 1951 Conservatives were split over his policies and evinced growing opposition to the authoritarian constitutional reforms he planned to impose in 1953. Gómez inactive after November 1951 because of bad health, resumed direct control of the presidency on June 13, 1953, but was overthrown on the same day by Gen. Gustavo Rojas Pinilla, Conservative chief of the military forces. The constitutional assembly, called for 1953 by Gómez, approved Rojas as provisional head of government and then elected him president for the 1954-58 term.

Rojas, nationally welcomed as a harbinger of peace, justice, and liberty, forgot his promises and merely replaced the dictatorship of Gómez with his own. Gradually the Liberal and Conservative parties reconciled their differences and formed the National Front to restore civil constitutional government. The coalition, based on a 50-50 split of government offices and rotation of the presidency, was later given an expiration date of 1974. Arrest of the National Front presidential candidate on April 30, 1957, started a series of demonstrations capped by a national economic strike. The armed forces acted as broker between president and National Front and on May 10, 1957, Rojas resigned after appointing a military junta to oversee transition to a popularly elected government. The junta faithfully fulfilled its assigned role. The agreements establishing the National Front were made part of the constitution by a plebiscite on Dec. 1, 1957. On July 20, 1958, Congress met for the first time since 1952 and Alberto Lleras Camargo, Liberal leader and major architect of the National Front, took office as president on Aug. 7, 1958. President Lleras ended the state of siege (1949-58) in most of the country, violence was sharply reduced, and the grave socioeconomic condition of the country improved.

During the Lleras administration an agrarian reform law was enacted. It provided for the breaking up of large estates on which the land was inadequately used and for the redistribution of this land in smaller plots to landless peasants. In May 1962 Guillermo León Valencia, candidate of the National Front, was elected president of the country. While Valencia was on a state visit to Venezuela in August 1963, government troops arrested former President Rojas and several of his supporters, charging them with plotting to seize control of the government. Rojas was removed to a remote military base.

Late in 1963, President Valencia's administration underwent a period of crisis caused mainly by a deterioration in the domestic economy. The situation forced Congress to grant limited decree authority to the president from August to December 1963 in financial, budgetary, and administrative matters. During this period, President Valencia issued decrees on taxation and judicial reform and created a monetary board, which took over control of bank credit policy and the monetary system on Nov. 1, 1963.

During 1964 and 1965 currency speculation and a shortage of foreign exchange led to a deterioration of the country's political and economic situation. Congress could not enact the reform measures that it considered necessary because of the rule that a two-thirds majority was required to pass major legislation. Rioting by university students in 1965 caused President Valencia to declare a state of siege, during which time he decreed the legislation that Congress had been unable to enact.

Congressional elections took place in March 1966, and the National Front won a decisive victory, gaining 58% of the total votes but still failing to achieve a two-thirds majority in the legislature. The presidential election followed in May 1966, and Carlos Lleras Restrepo, the National Front candidate, won easily with 71% of the votes.

## V. POPULATION

The census of 1951, taken during a period of violent internal strife, reported the population of Colombia to be 11,548,172, a density of 26.3 persons per square mile; pop. (1964 census) 17,484,508. The majority of Colombia's population lives in the western one-third of the country and is concentrated on the slopes and in the valleys of the central and eastern ranges of the Andes, which run from north to south throughout the western portion of the

country, and along the Caribbean coastal plain. On the other hand, the hot, humid areas along the Pacific coastal plain are sparsely populated, and the vast areas of plains and jungle that lie east of the Andes are practically uninhabited.

Persons of the white race, or intermixtures of the white and Indian or white and Negro, in which white features predominate, constitute the majority of Colombia's population. Negroes and mulattoes probably make up about 18% of the total, and mestizos another 57%. The Negroid elements are concentrated in the settlements along the Caribbean coastal plain, in the Magdalena and Cauca valleys, and in the extensive lowland areas along the Pacific. The largest proportion of Indians and mestizos is found in the southernmost department of Nariño, on the Guajira Peninsula, and at the highest elevations in the mountains throughout the country. They are also present in substantial numbers in Bogotá, Tunja, Pasto, and some of the other capitals, and they constitute almost the sole inhabitants of the more remote sections east of the Andes. The white and predominantly white population is heavily represented in all of the cities, throughout the densely populated mountainous districts that lie north of Bogotá, and in most portions of the departments of Antioquia and Caldas.

Area and Population of Colombia by Major Civil Divisions

Political subdivision and capital city	Area (square miles)	Population	
		1951 census	1964 census
Departments

\*Became a department on July 18, 1952; until then it was part of department of Bolívar.  
 †A department since Nov. 10, 1964; was an *intendencia*. ‡A department since Jan. 7, 1966, was part of department of Caldas. §New department, to be approved by the president. ¶A department since Aug. 30, 1966; was part of department of Caldas. ¶Was incorporated into department of Boyacá on Oct. 1, 1953. ¶Became a *comisaria* on July 13, 1963; was part of *comisaria* of Vaupés.

Because of its high birth and death rates, Colombia's population is concentrated in the younger ages, about 43% being less than 15 years of age; 54%, aged 15 to 64; and only 3%, 65 or over.

In 1938, 29% of the population was urban (i.e., living in towns of 1,500 or more inhabitants). By 1951 this percentage had risen to 39. After that date the trend toward urbanization continued, speeded up by the wave of violence that began about 1948 and which cost hundreds of thousands of lives.

After 1938 Colombia's population increased by about 2.5% annually. Since immigration is a negligible factor in Colombia, the rate of natural increase appears to be very high. Estimates place the birthrate at about 42 and the death rate at approximately 13 per 1,000 population. (T. L. SH.)

## VI. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Government.**—Under the constitution of Aug. 5, 1886, which was revised and codified in 1945, the executive branch is formed by the president and 13 cabinet ministers and the govern-

nors of the departments, who are appointed by the president, as well as other administrative authorities directly or indirectly controlled by him. The president is elected by the people for a term of four years, and he may not succeed himself. Attached to the president is a seven-member consulting body known as the Council of State.

The legislative power, according to the constitution, is vested in Congress, consisting of the Senate and the House of Representatives. The Senate is composed of three or more members from each department (one for each 190,000 population), popularly elected for four-year terms. The House of Representatives is composed of three or more members from each department (one for each 90,000 population), popularly elected for two-year terms. All Colombians over 21 years of age are citizens; women were expressly barred from voting and holding elective office under the constitution until an act passed Aug. 25, 1954, by the national constituent assembly gave them the right to vote.

The judicial power is vested in the Supreme Court at Bogotá and a superior court in each judicial district. The Supreme Court has appellate jurisdiction in judicial matters and original jurisdiction in impeachment trials and in matters involving constitutional interpretation. There are various lower courts.

The country has been divided for many years into departments, *intendencias* (intendancies), and *comisarias* (subdelegations). The departments have popularly elected assemblies; the *intendencias* and *comisarias* are administered directly by officials appointed by the central government.

**2. Living Conditions.**—The cost of living in Colombia rose only 9% between 1953 and 1956, but by 1960 was up 69% over 1953 and continued to rise during the 1960s. Slightly more than 3,000,000 Colombians were gainfully employed and of this figure, approximately half were occupied in agriculture, hunting, and fishing. Labour conditions were a major political issue in Colombia during the 1930s, when unions played significant roles in national politics. In the 1960s about 10% of the country's workers were members of unions affiliated with the Confederation of Colombian Workers (C.T.C.).

**3. Welfare Services.**—Colombia's social security programs, many of which date from the administrations of President López, include provision for health and maternity benefits, compensation for workmen injured during the course of their employment, and allowances for persons unable to work.

**4. Health.**—In general, the coast and lower river valleys are unhealthful but there are regions that form exceptions, including the cities of Barranquilla and Santa Marta. In the low country, malaria and dysentery are prevalent. The Magdalena Valley is particularly unhealthful because of the vast swamp areas and the resultant mosquitoes. Hookworm is common.

Colombia lacks many sanitary facilities, but in many communities this situation, aggravated by the rapid growth in population, was being corrected in the latter half of the 20th century. The ports are generally free from yellow fever and similar diseases. In coping with these problems Colombia, since the early 1940s, participated in many of the bilateral technical assistance programs of the United States.

**5. Education.**—The constitution provides that public education shall be organized and directed in agreement with the Roman Catholic religion and that primary education, paid for out of the public funds, shall be free but not obligatory. Primary education is under the control of the departments, and the status of education varies in the different departments. At the end of the 19th century the proportion of illiterates was authoritatively estimated at 90%. By the 1960s this figure had been reduced to about 35%. Higher education is provided by the National University of Bogotá (founded 1573), and also by 13 universities in the capital and 14 elsewhere.

**6. Defense.**—Military service for one year is compulsory between the ages of 21 and 30. Peacetime strength of the Army varies between 12,000 and 15,000. The Navy consists of destroyers, frigates, river gunboats, and various smaller vessels. The Air Force has a considerable number of aircraft of various types. Colombia was the only South American country to participate in

the Korean War, contributing an infantry regiment. Also, its frigates participated in the Korean blockade. (X.; G. I. B.)

## VII. THE ECONOMY

About 70% of Colombia's export trade is dependent on one crop, coffee, with the result that lower prices in the world market give rise to balance of payments crises. Under quota agreements with coffee-producing and consuming countries in the early 1960s, Colombia's export of coffee was limited. In spite of efforts to diversify the economy, the dominance of one crop remained and an increasing amount of small domestic industry did not appreciably change the situation. Economic development has also been hindered by inadequate means of transport resulting from the difficulty of the terrain. To facilitate problems of production, tariffs, and trade, Colombia joined the Latin American Free Trade Association in October 1961.

**1. Production. Agriculture.**—The larger part of the population lives by farming and cattle herding. Coffee production is the principal source of wealth. Only about 2% of the land was under cultivation in the mid-1960s and there were still vast tracts of virgin land in all the departments. The largest proportion of cultivated land is at elevations of 3,000 to 10,000 ft. (900–3,000 m.), where altitude modifies the climate to give a temperate zone. Hand methods of cultivation, principally use of the machete and hoe, are predominant, but mechanization has made some progress, particularly on larger farms. One-crop farming is widespread. A considerable acreage of land is under irrigation, almost entirely by privately developed systems, mostly using diversion canals.

Coffee is grown principally in the temperate zone between 3,000 and 6,000 ft. Production greatly increased at the beginning of the 20th century and Colombia came to be second in importance only to Brazil as a world producer. Colombian coffee is known as "mild" and is blended with Brazilian and "robusta" types. It is grown under shade trees, largely on mountain slopes, predominantly by small growers. The departments of Caldas, Antioquia, Tolima, Cundinamarca, and Valle del Cauca are the principal producing regions. Wide control over the industry is exercised by the Federación Nacional de Cafeteros (National Federation of Coffee Growers), a cooperative association founded in 1927, which provides easy credit and large central warehouses.

Bananas grow easily in nearly all regions of the tropical and temperate zones in a great number of varieties and, besides being an increasingly important export, are one of the principal foods of the people. Other agricultural exports are sugar, cotton, tobacco, and timber, but their export value is insignificant. The

tropical zone produces rubber, coconuts, tobacco, bananas, sugarcane, corn (maize), cotton, cocoa, beans, rice, etc. The subtropical zone, in addition to coffee, produces a great variety of fruits, such as bananas, pineapples, mangoes, papayas, alligator pears (avocados), pears, and citrus fruits. The temperate zone is most favorable for agriculture and produces, besides coffee, wheat, barley, potatoes, oats, corn, and most of the fruits and vegetables known in the United States and Europe. Exports of bananas declined during World War II because of restricted markets and the ravages of Sigatoka disease. A steady recovery took place after the war, while some of the diseased banana lands were converted to the cultivation of cotton and African palm. Banana exports rose appreciably as a result of an important banana development program which was begun in Urabá in September 1962.

The largest rural properties are those devoted to cattle raising, and in the eastern llanos at the subtropical altitude there are vast areas suitable for this activity. It is estimated that with adequate development the country could support 50,000,000 head. Both cattle and hides are exported.

**Mining.**—Gold, formerly the principal source of mineral wealth, has been supplanted by petroleum. The main concessions are those of De Mares, Barco (Colombia Petroleum Company), and Yondo (Shell). The De Mares concession, granted in 1921 to the Tropical Oil Company, a subsidiary of Standard Oil Company (N.J.), reverted to the government upon its expiry in August 1951 and was taken over by the government-sponsored Empresa Colombiana de Petróleos. There is a refinery at Barrancabermeja which serves the De Mares field, and a double pipeline 325 mi. (523 km.) long runs from Barrancabermeja to Mamonal near Cartagena. Another line extends from Oru in the Barco field to Coveñas on the Caribbean. Two additional lines, one from Puerto Berrío at the southern end of the main pipeline to Medellín and the other from Puerto Salgar to Bogotá, were built in the 1950s and one from Cúcuta to Santa Marta came into service in 1964.

Gold and silver are still produced in Colombia, mainly in the Antioquia region. Colombia has the largest known platinum deposit and is the world's chief source of fine-quality emeralds from the mines of Muzo and Cosquez in Boyacá Department.

Colombia's coal reserves are estimated at 20,000,000,000 tons, the largest in Latin America. The production of iron ore increased with the stimulus provided by the Paz del Río steelworks, completed in 1954. Other mineral reserves include salt, sulfur, limestone, zinc, mercury, antimony, and manganese.

**Industries.**—At the beginning of the 20th century, Colombia had only about 100 industrial establishments. Two world wars

and the encouragement of a protective tariff adopted in 1930 led, however, to extraordinary industrial development, and by 1950 national production met almost all the domestic requirements for textiles, footwear, cement and other building materials, some industrial chemicals, foodstuffs and beverages, and tobacco. By the 1960s the manufacturing industry was expanding at an annual average rate of 6-7%. The census of manufactures listed more than 11,000 enterprises. Geographically, industry was concentrated in and about the cities of Bogotá, Medellín, Cali, and Barranquilla. Industrial development continued to be hampered by inadequate transport and a lack of power facilities.

**2. Trade and Finance.**—Colombia, by reason of its geography, has a wide range of potential exports, but in the 1960s its export trade was confined within such narrow limits as to put it on the edge of the one-crop country group. The leading exports were coffee, petroleum, bananas, tobacco, platinum, and sugar, and the principal destination was the United States, which took about 50% of the total. Machinery, metals and metal goods, chemical products, textile goods, vehicles and equipment, and paper and its manufactures were the main imports, about 50% from the U.S.

The semiofficial Banco de la República was inaugurated in July 1923 as a central bank and the sole bank of issue. Under its contract it paid to the government a fixed royalty and 75% of its profits. The bank's organization and relation to the commercial banks of the country are based on the U.S. federal reserve system. The monetary unit is the peso, with a par value of \$0.512825 U.S. currency, or 0.455733 gr. of fine gold, as fixed by the International Monetary Fund on Dec. 17, 1948. This parity is equivalent to 1.95 pesos to U.S. \$1. However, the exchange reforms of June 17, 1957, created a free market for funds other than those connected with trade operations, and in 1958 the free market quotation averaged 7.59 pesos per U.S. \$1. In the period January 1963 to September 1964 the Banco de la República intervened in the free market and maintained the rate at about 10 pesos to U.S. \$1. On March 26, 1958, a system of auctions was introduced for the sale by the Banco de la República of exchange certificates, export

earnings being purchased at a controlled rate and certificates offered at auction.

**3. Transport and Communications.**—The transport problem in Colombia is one of peculiar difficulty. With few exceptions, the more densely populated districts are in the interior, isolated from the coast by mountain chains, and communications in the 1960s were still inadequate. Navigation on the Magdalena River is slow and open only to vessels of small draft, necessitating transshipment at Barranquilla, where the harbour was improved in the 1930s. A peculiar feature of Colombian transport is the use of aerial cables for handling merchandise and passengers. Three of these, with a total length of 88.2 mi. (142 km.) are in operation between Gamarrá and Ocaña, Manizales and Mariquita, and in the department of Caldas.

**Roads.**—Three main highways run from north to south: the Tronco Occidental, Tronco Oriental, and Tronco Central. Most important is the Oriental, the Colombian section of the Pan-American and Simón Bolívar highways. Other roads of varying quality connect Bogotá with other interior cities. In the 1950s and 1960s Colombia was engaged in a program to extend and improve its national highway network, in particular the 1,860 mi. (2,993 km.) providing connections between the main cities and the principal ocean and river ports.

**Railways.**—The railway system in the early 1960s comprised 17 distinct, and in many cases unconnected, lines built to link the Caribbean and Pacific ports and the Magdalena River ports with the interior centres. Two lines running north from Bogotá were narrowed from metre to three-foot gauge in 1952. In January 1954 nationalization of all railroads was agreed upon. A new railway 418 mi. (673 km.) long was opened in 1961 to connect Santa Marta on the Caribbean with the interior of the country. In 1963 the World Bank granted a loan to help finance a ten-year program of railway modernization.

**Shipping.**—Barranquilla, at the mouth of the Magdalena, is the country's largest port. Others include Cartagena and Santa Marta on the Caribbean and Buenaventura on the Pacific, which increased in importance during the 1950s. Frequent and regular ship service by several lines is available to Panama, New York City, New Orleans, and European ports. In 1946 Colombia, Ecuador, and Venezuela formed the Flota Mercante Gracoloniana, which operates a fleet of oceangoing vessels, but in 1953 Venezuela withdrew; Colombia owns 80% of the assets.

**Air Transport.**—Colombia was the first South American country to develop air transport on a commercial scale. In 1920 a concession was granted to the German-Colombian Company, Sociedad Colombiana-Alemana de Transportes Aéreos (known as Scadta), which was taken over after the outbreak of World War II by Aerovías Nacionales de Colombia (Avianca). After the war, expansion was rapid, and Colombia is now covered by a network of air routes with excellent international connections. In the mid-1960s more than 25 companies were operating in the country with Avianca flying most of the internal routes. The number of airfields exceeded 400.

**Telecommunications.**—Both telegraph and radio systems are government-operated. The larger cities have local telephone services owned by private companies or the municipalities. The national government owns long-distance telephone lines connecting most of the larger cities. External cable communication is through Buenaventura and Cartagena.

**COLOMBIÈRE, CLAUDE DE LA** (1641-1682), French Jesuit, who assisted St. Margaret Mary Alacoque (q.v.) in establishing the devotion to the Sacred Heart (q.v.), was born Feb. 2, 1641, at St. Symphorien d'Ozon in Dauphiné. He received his early education from the Jesuits of Lyons, and entered their novitiate at Avignon in 1658. He studied theology at the Collège de Clermont in Paris.

After ordination his first appointment was to the chair of rhetoric in the Collège de la Trinité at Lyons (1670-73). In 1675 he was appointed superior of the small Jesuit college at Paray-le-Monial. There he may be said to have earned his greatest claim to renown by his enlightened spiritual direction of St. Margaret Mary Alacoque. In 1676 he was appointed court preacher to Mary of Modena (Maria Beatrice d'Este), who had become duchess of York by her marriage with the future James II, and in October took up his residence in St. James's Palace, London. He remained at this post until falsely accused by a former protégé of complicity in the Titus Oates affair. After an imprisonment of five weeks he was released but was obliged to return to France, where he died on Feb. 15, 1682, of a disease of the lungs contracted before his imprisonment. He was beatified on June 16, 1929.

Colombière's complete works were published in six volumes at Grenoble in 1900-01; they include four volumes of sermons, one of sermon notes and one of correspondence. (W. J. Y.)

**COLOMBO, MATTEO REALDO** (1516?-1559), Italian surgeon and anatomist, was one of several Renaissance figures who anticipated William Harvey in the discovery of the pulmonary circulation (the flow of blood from the heart to the lungs and return). He was born in Cremona, studied philosophy and liberal arts in Milan and was then apprenticed to a Venetian surgeon for seven years. Following this, he studied medicine at the University of Padua (1540). Andreas Vesalius, founder of modern anatomy and then professor of surgery (which included anatomy) at Padua, was impressed with Colombo's skill and appointed him prosector. When Vesalius left Padua in 1543, Colombo succeeded him to the chair. He turned bitterly against his former teacher and was among the most violent of the enemies and detractors whose attacks crushed the spirit of Vesalius.

From Padua, Colombo went to Pisa to become the first professor of anatomy there, and subsequently to Rome. In the capital he taught at the Sapienza, became surgeon to Pope Julius III and prepared his book *De re anatomica* (1559), in which his views on the pulmonary circulation are clearly expressed. This subject had been dealt with in a Spanish publication by Juan Valverde, a pupil of Colombo, who gave full credit for the discovery to his teacher. Colombo died in 1559.

See E. A. Cappola, "The Discovery of the Pulmonary Circulation:

A New Approach," *Bulletin of the History of Medicine*, 31:44-77 (1957). (L. M. Z.)

**COLOMBO**, the capital and principal seaport of Ceylon, lies on the west coast of the island just south of the mouth of the Kelani river. Pop. (1963) 510,947. It is also the administrative centre of Western province and of Colombo district. The environs of the city are low lying and considerable protective works have been constructed against floods. The climate is warm and humid, the mean temperature being 80.8° F. and the mean annual rainfall 91 in. The oldest part of the city is the *pettah*, where much commercial development took place after World War II. The administrative and commercial buildings are centred in the site of the Fort, built by the Portuguese at the southern end of the present harbour. Queen's house, which is the residence of the governor general, and the main block of government offices are in this area. The law courts stand in the suburb known as Hultsdorf which during the Dutch occupation formed, with Wolfendahl, the principal European quarter. The latter suburb contains the Dutch church. An important Buddhist temple is at Kotahena, and the Ponnambalavanesar Hindu temple is at Kochikade. The city is well served with several primary and secondary schools. In 1942 the Ceylon University college and the Medical college were merged to constitute the University of Ceylon, and all the faculties except those of engineering and medicine were moved to Peradeniya, near Kandy. In 1959 the Vidyodaya and Vidyalankara *pirivenas* (seats of Buddhist learning) were raised to university status. Vidyodaya university is within the city while Vidyalankara is at Kelaniya, 4 mi. outside. Kelaniya is also the site of a Buddhist temple and is a place of pilgrimage. In the city are the Pasteur institute, the Medical Research institute, the Scientific and Industrial Research institute and a museum. Following Ceylon's attainment of independence in 1948 Independence hall was built in Kandyan style in Independence square. The modern residential part of the city stretches south along a strip of land between the sea and the low-lying land parallel to the coast. Besides the Galle Face esplanade, south of the Fort, the main open spaces are Victoria park, Campbell park, Havelock park, the Havelock racecourse, the Ridgeway golf links and the Colombo oval, the best known of the cricket fields. Mount Lavinia is a favourite sea-bathing and pleasure resort. The suburb of Kotte, 5 mi. from the port, was one of the former capitals of the Sinhalese kings, and the suburb of Mutwal, north of the harbour, is chiefly inhabited by fishermen, many of whom are Roman Catholics.

Colombo is connected by rail with most of the larger towns in the island, including Jaffna and Trincomalee. The Kelani river is spanned by the Victoria bridge, from which roads lead north to Negombo and Jaffna and northeast to Kandy. The New Kelani bridge carries six lanes of traffic. To the south main roads follow the coast to Hambantota and the Kelani valley to Avissawella. The airport at Ratmalana links Colombo daily with several provincial towns and with India, and almost daily with the rest of the world. The Katunayaka airport, used by larger aircraft, is 18 mi. away.

**The Port.**—Until 1874, when the building of the breakwater and other harbour works were begun in Colombo, Galle (70 mi. S. by rail) was Ceylon's chief port. Although it is one of the biggest artificial harbours in the world (602 ac. at low water), Colombo lacked many of the facilities essential for a large port until 1950, when modernization was begun. By 1957 four quays (Queen Elizabeth, Prince Vijaya, Delft and Mutwal, with a fisheries harbour), an oil dock and an articulated oil boom had been completed. Vessels drawing 34 ft. can enter by the western channel and vessels drawing 29 ft. can enter by the northern channel. Berthing accommodation is available for 45 vessels during the northeast monsoon and 39 vessels during the southwest monsoon. Beira lake and the canal connecting it with the harbour are an integral part of the port. The canal is navigable by 100-ton barges. Colombo is one of the busiest ports in the commonwealth. Its chief exports include tea, rubber, cacao, coir, copra and coconuts; its main imports are rice, cotton piece goods, sugar, milk foods and manures.

COLOMBO DISTRICT has three municipal councils, Colombo,

Negombo and Mount Lavinia. Its population was 1,708,726 in 1953 and its area is 808 sq.mi. (M. J. T.)

**COLOMBO PLAN**, an arrangement for discussing national economic development plans, providing technical assistance and financing particular developmental projects for south and south-east Asia, established at Colombo, Ceylon, in June 1951 following discussions by the governments of India, Pakistan, Ceylon, Australia, New Zealand and Great Britain. Later the United States, Japan and a number of countries in southeast Asia joined the organization.

The basic work is done at one annual meeting. A continuing body deals with technical assistance. Financing of development projects is arranged bilaterally between individual governments or with the International Bank for Reconstruction and Development. See FOREIGN AID PROGRAMS. (C. P. K.)

**COLÓN**, department on the Caribbean sea in eastern Honduras. Pop. (1961) 41,904; area 3,426 sq.mi. It consists mainly of lowlands, with an annual rainfall of well over 100 in. Most of the population is concentrated in the fertile and less rainy Aguán valley and coastal plain in the northwestern part of the department. Pine savanna on poor soils in the east and mixed hardwoods elsewhere provide lumber for domestic use and for export. Crop production, mostly in the northwest, includes rice, manioc (yuca, cassava), sweet potatoes and bananas, which are exported through the port of Trujillo, the departmental capital (pop. 3,460), and Puerto Castilla. (C. F. J.)

**COLÓN**, a province on the northern coast of Panamá, lying both east and west of the Canal Zone. Pop. (1960) 105,416; area 2,882 sq.mi. The population, which is about 58% urban, is concentrated in areas near the Canal Zone, where there are also important agricultural districts and some manufacturing establishments. Twenty miles to the east of Colón city, the provincial capital, is Porto Bello (*q.v.*), which during the colonial period was a strongly fortified town at the northern end of the Old Gold road. (C. F. J.)

**COLÓN**, the second city of Panamá and the northern gateway to the Panama canal. The port of Cristóbal, which is within the Canal Zone, is virtually a suburb of Colón. The great port works and docks built by the U.S. government at Cristóbal make Colón one of the most important ports of the Caribbean sea. A considerable portion of the freight for neighbouring coastal points in Central America and northern South America is transhipped there and other goods are unloaded for storage in the large bonded warehouses in Colón.

Colón had a population (1960) of 59,598, not including the residents of the Canal Zone, but about 40% of the gainfully employed persons of Colón work in the Canal Zone. Colón is the northern terminus of the Panama railroad, 48 mi. from Panamá city, and is on the modern Trans-Isthmian highway. It is the seat of a customhouse and of consuls of various countries, and is the capital of the province of Colón.

Colón is one of the busiest tourist centres in the world and its streets are lined with shops owned by peoples of all nationalities selling varied products from all over the world. Front street is a well-known shopping centre. The population is largely Negro, chiefly descendants of labourers imported from the British West Indies during the various periods of construction on the Panama canal. The residents include a wide range of racial mixtures and the languages of three continents are heard on the streets.

The town was founded in 1850 at the Atlantic terminus of the original Panama railway, and was first called Aspinwall after William H. Aspinwall (1807-75), one of the builders of the railway. Colón is the Spanish form of Columbus, and the name of the twin city of Cristóbal is Spanish for his Christian name. On the completion of the railway in 1855, Colón attained outstanding importance as compared with the older Caribbean ports of Panamá, and with the first plans for the isthmian canal it took on additional prestige. Prior to the beginning of work on the canal Colón, built on swampy Manzanillo Island, was notoriously unhealthy, and one of the provisions of the canal treaty of 1903 gave the United States full sanitary control over the cities of Panamá. Much of the work of Col. William C. Gorgas (*q.v.*),

the sanitary genius of the canal construction, was done in and about Colón, which was given a new system of waterworks and sewerage as well as complete drainage of the surrounding swamps in the triumphant fight against yellow fever and malaria. Colón thus became one of the most healthful tropical cities in the world. Most of the streets of Colón are paved and kept clean.

Colón has large public buildings, several modern hotels, several churches, three modern hospitals and three theatres. See PANAMA CANAL. (W. THO.; W. FT.; C. F. J.)

**COLÓN, ARCHIPIÉLAGO DE**: see GALÁPAGOS ISLANDS.

**COLON**, in anatomy, the portion of the large intestine that extends from the caecum to the rectum.

See GASTROINTESTINAL TRACT.

**COLONEL**, traditionally the commanding officer of a regiment, is the highest officer rank below the general officer grades in most armies, or below brigadier in the British services. In air forces that use the same titles of rank as the army, such as the U.S. air force, a colonel's command is usually a group; the comparable grade in the Royal Air Force is group captain. When not exercising command of a regiment, group or equivalent formation, a colonel is generally placed in a senior staff or administrative post.

In a U.S. army reorganization announced in 1957 infantry regiments were eliminated as combat units and reformed into battle groups (*see* REGIMENT), each under the command of a colonel. In an armoured division a colonel's command was called a combat command; it consisted of a variable number of units of mixed forces, including infantry, armour, artillery and supporting services. In the U.S. artillery a colonel's command was called a group and was made up of three or four separate battalions.

A further reorganization of the U.S. army in 1961 called for elimination of the battle group, making the brigade (*q.v.*) the tactical unit between the division and the battalion. The brigade was to be a colonel's command in peacetime, a brigadier general's command in wartime. Divisional support commands and various nondivisional units, usually referred to as groups, were also to be commanded by colonels.

In the 17th and 18th centuries the colonelcy of a British regiment of infantry or cavalry implied a proprietary right in the organization (*see* OFFICERS, MILITARY). Whether or not the colonel commanded the regiment in the field, he always superintended its finances and interior economy, usually to his profit. In time of war the sovereign invariably selected the generals for his armies from among the proprietary colonels. Meanwhile, active field command of such a regiment was exercised by its lieutenant colonel. As the grade of general became permanent, many generals retained their proprietary colonelcies.

All British regiments have a senior officer (serving or retired), styled "colonel of the regiment." His duties are confined to certain specified domestic matters of purely regimental concern. He may be any rank above lieutenant colonel, but is usually a general. (Some corps and regiments have a colonel in chief, who is always a member, male or female, of the British or a foreign royal family. His duties are formal and confined mostly to ceremonial and social occasions.) (T. N. D.)

**COLONIA**, a department on the Río de la Plata in southwest Uruguay, is important historically and economically. Pop. (1963) 104,795; area 2,194 sq.mi. Its capital, Colonia (pop. [1962 est.] 19,202), the first permanent settlement in Uruguay, was founded by Portuguese soldiers from Brazil in 1680. The Spanish eventually captured Colonia and then moved their defense headquarters to a more strategic location, Montevideo, founded in 1726.

Colonia city, the Uruguayan port closest to Buenos Aires, is a tourist centre and a railroad terminus. Truck farming, dairying, first introduced by Swiss colonists, and textiles make Colonia one of the richest and most densely populated departments in Uruguay. (M. I. V.)

**COLONIAL ARCHITECTURE** refers, broadly, to the architecture of any people transplanted from a country but remaining subject to it. The peculiar characteristics of colonial architecture result from the attempt to reproduce as closely as

possible the architecture of the mother country in places where labour may be limited, untrained or influenced by native tradition, materials may be different and climate and environment may be unfamiliar. This article is confined to a discussion of North American colonial architecture.

The colonial architecture of early North America was as diverse as the peoples who settled the new continent: English, Dutch, French, Swedish, Spanish, German, Scotch-Irish. Each group brought the style and building customs of the mother country, adapting them as best it could to the materials and conditions of a new land. Thus there were several colonial styles. The earliest buildings of all but the Spanish colonists were medieval in style: not the elaborate Gothic of the great European cathedrals and manor houses, but the simple late Gothic of village houses and barns. These practical structures were well adapted to the pioneer conditions that prevailed in the colonies until about 1700, and few changes were needed to adapt them to the more severe climate. The styles were frank expressions of functional and structural requirements, with only an occasional bit of craftsman's ornament. So far as is known, no single new structural technique or architectural form was invented in the American colonies.

There were seven reasonably distinct regional colonial styles: (1) The New England colonial, visible in almost a hundred surviving 17th-century houses, was predominantly of wood construction with hand-hewn oak frames and clapboard siding; its prototypes are to be found chiefly in the southeastern counties of England. (2) The Dutch colonial, centring in the Hudson valley, western Long Island and northern New Jersey, made more use of stone and brick, or a combination of these with wood; its prototypes were in Holland and Flanders. The style persisted in this region until after the Revolution. (3) The Swedish colonial settlement, established in 1638 along the lower Delaware river, was of short duration, but it contributed the log cabin (in the sense of a structure with round logs, notched at the corners and with protruding ends) to American architecture. (4) The Pennsylvania colonial was late in origin (the colony was not founded until 1681) and rapidly developed into a sophisticated Georgian mode, based on English precedents. A local variant, often called Pennsylvania Dutch, evolved in the southeastern counties where Germans settled in large numbers after 1710. (5) The Southern colonial flourished in Maryland, Virginia and the Carolinas. Story-and-a-half brick houses, sometimes with large projecting end chimneys and decorative brick masonry, prevailed. (6) The French colonial, stemming from medieval French sources, evolved in the maritime provinces and the St. Lawrence valley. The earliest impressive structure was Champlain's Habitation built at Port Royal, Nova Scotia, in 1604. Most of the surviving early houses of New France are to be found in the province of Quebec. The French settled the Illinois country in 1695 and later, using the Quebec style. Far to the south, Louisiana was established as a colony in 1699, and New Orleans became the capital in 1718. There grew up a distinctive regional style in the close-packed streets of the *Vieux Carré* of New Orleans and in the quiet plantations of the bayou country. (7) The Spanish colonial extended geographically and chronologically from St. Augustine in 1565 to San Francisco in 1848. The five great mission fields were in Florida, New Mexico (1598 on), Texas and Arizona (1690 on) and California (1769 on). Unlike other colonial styles, which were medieval, the Spanish colonial followed the Renaissance and baroque styles of Spain and of early Mexico. (See *IBERO-AMERICAN ARCHITECTURE*.)

By 1700 the colonies of the Atlantic seaboard were united under English rule, and the architectural style of the 18th century was completely different from that of the 17th century. See *GEORGIAN ARCHITECTURE*; see also references under "Colonial Architecture" in the Index volume.

See Hugh Morrison, *Early American Architecture* (1952).

(H. M.)

**COLONIAL DEVELOPMENT CORPORATION**, a British public corporation established under the Overseas Resources Development acts, 1948–58, for the purpose of assisting British colonial territories in the development of their economies.

It has borrowing powers to a maximum of £150,000,000 long-term and £10,000,000 short-term outstanding at any one time. It is a commercial organization and is required to pay its way, but there is no share capital; the loan money has been borrowed from the U.K. treasury; interest has to be paid over the life of each loan at the rate current at the time of each advance. On long-term loans interest payments are postponed for the first seven years; loans and interest are repayable by 33 annuities starting in the eighth year.

At the end of 1957 there were 76 projects in hand in 23 territories, covering agriculture, animal products, factories, fisheries, forestry, hotels, minerals, property and housing, electric power, transport and communications. Some were managed by the corporation directly, others by private enterprise associates; some were loans made to industrial concerns and public corporations. Total capital approved for these projects was £80,468,000.

The corporation prefers to arrange for financial participation and management by experienced private enterprise rather than to finance and manage projects on its own. Association with territorial governments is also sought, and fullest possible use is made of local experience and capital.

Corporation directors are appointed by the secretary of state for the colonies and serve part time. Under the general manager are five controllers at the head office, and there are six regional controllers in the Caribbean, far east, east Africa, central Africa, high commission territories and west Africa.

**COLONIAL OFFICE**: see *GOVERNMENT DEPARTMENTS: Great Britain*.

**COLONIAL PREFERENCE**: see *IMPERIAL PREFERENCE*.

**COLONNA**, a noble Roman family of great antiquity and foremost in importance, is descended from the 10th-century counts of Tusculum. The first to take the name Colonna ("de Columna") was Piero, the son of Gregorio, count of Tusculum, who on Gregorio's death (c. 1064) received the castle of Colonna in the Alban hills, together with Palestrina and other places, as his share of the inheritance. Like other Roman families, the Colonna gained power and wealth through papal favour and by the 13th century were already providing cardinals and senators of Rome. Thereafter the Colonna are so consistently prominent in the politics of the church and the city of Rome that even the most distinguished are far too numerous to name; a detailed record of the family would almost amount to a history of Lazio and of Rome itself. Throughout the middle ages they figure among the most unruly and potent of the Roman baronial dynasties; their feuds with the Caetani and Orsini dominate the local history of a region where feudal power long remained unsubdued. Of more than local importance, however, was their bitter quarrel with the Caetani pope, Boniface VIII, who tried to extirpate the family and drove them into alliance with his enemy, the French king Philip IV the Fair; Sciarra Colonna led the armed attack on Boniface at Anagni on Sept. 7, 1303. On the pope's death the Colonna recovered their lands and influence, and for many years subsequently Rome was harassed by their struggle for power with the Orsini, which divided the nobility into two contending factions. These conditions gave rise to Cola di Rienzi's popular dictatorship, which was a check to all the Roman magnates and notably the Colonna, over whom the tribune won a bloody victory at Porta San Lorenzo in Rome on Nov. 20, 1347. The check, however, was temporary; Colonna power was undiminished and not long after was signally increased by the election of Constance of Cardinal Oddone Colonna as Pope Martin V. During his pontificate (1417–31) Martin obtained the grant of fiefs for his family in southern Italy and enriched them with vast estates in papal territory, which included Frascati, Paliano, Genazzano and many other places. Their power was challenged by Martin's successor, Eugenius IV, and for well over a century the fortunes of the Colonna continued to be disturbed by conflict with the popes; but from the later years of the 16th century they lived in unbroken peace with the papacy, and many members of the family rose to eminence as prelates,

soldiers and statesmen in the service of the church as well as other powers, particularly Spain.

The surviving branches of the family comprise the Colonna di Paliano, the Colonna di Stigliano and the Barberini-Colonna di Palestrina, who took the surname Barberini in consequence of the marriage of Giulio Cesare Colonna, prince of Carbognano, with Cornelia Barberini in 1728.

**COLONNA, VITTORIA** (1492–1547), Italian poet whose contemporary reputation derived more from her personal than her literary gifts, and whose permanent fame is assured by her friendship with Michelangelo (*q.v.*), was born in Marino, near Rome, the daughter of Fabrizio Colonna, grand constable of the kingdom of Naples, and Agnese di Montefeltro, daughter of Duke Federigo d'Urbino. In 1509 she married the marquis of Pescara, who died in 1525. A lady of intelligence and learning, much given to meditation and possessing a deeply emotional nature (held in check by her aristocratic education), she was ranked during her lifetime above all other contemporary women writers. Both her religious and her love poems, written according to the Petrarchan pattern, are, however, disappointingly conventional. Even her letters are uninteresting, although, except for those addressed to distinguished people, such as the two to Charles V, they were not originally meant for publication (only ten were published during her life). She owes her lasting renown to her platonic friendship with Michelangelo and to her interest in such religious reformers as Juan de Valdés and Bernardino Ochino. After having retired to live in the Benedictine convent of Saint' Anna de' Funari, she died in the Palazzo Cesarini, Rome, on Feb. 25, 1547.

**COLONNADE:** see COLUMN; ORDER.

**COLONSAY AND ORONSAY**, islands of western Scotland within the Jura and Colonsay district, lie 35 mi. S.W. of Oban, Argyll, facing the open Atlantic ocean. Population of the district in 1961 was 415. The islands (area 17 sq.mi.) are named for Saints Columba and Oran and are rich in archaeological and medieval Christian remains. They are separated by a narrow sound and are joined at low tide. Although the surface is generally rough, there are several farms and the tillage ratio to total area is 1:56. Soil is derived from the lower, more fertile strata of the Torridonian sandstone. There is still some natural scrub woodland, a rare phenomenon in the Hebrides. The garden of Colonsay house (1722), of great beauty, enjoys such shelter that many exotics are grown. A large and old-established colony of Atlantic seals occupies the southwest of Oronsay. A weekly steamer from Oban stands by if the weather allows. (F. F. Dg.)

**COLONY** is a term having two distinct meanings. Sometimes it is used to describe the compact settlement of a group of nationals of one country within the territory of another while the settlers remain loyal to the mother country. Thus writers refer to German colonies in Brazil and Chinese colonies in Indonesia. More frequently, however, colony refers to a nonself-governing territory and has become a term denoting disapproval and impatience among critics of European overseas policy with the political status of certain such territories in Asia, Africa and the Caribbean. This status is said to be the result of colonialism or imperialism, processes increasingly considered immoral and illegal by many nations and the subject of constant bitter debate among governments after World War II.

Definitions of colony differ appreciably according to the political opinions held. The modern colonial powers—Great Britain, France, the Netherlands, Belgium, Portugal, Australia and the U.S.—prefer a definition derived from their national laws. A

colony, also described as a dependency without full self-government, is considered by the various governing powers to be a territory under the administrative jurisdiction of the mother country, prevented by social, economic and political backwardness from being fully in charge of its own decisions. Laws are made by the mother country and enforced by officials sent out from there, even though the colony may enjoy representation in the home legislature (the French and Portuguese practice). Critics of modern colonialism, and especially the peoples of Asian, African and Latin-American countries, on the other hand, prefer a more sweeping definition. They consider a colony any territory that is under the overwhelming economic or political influence of another country. Thus they considered China between 1900 and 1930 as a colony of the west because of the economic dominance of certain European and American countries and the impotence of the central Chinese government, sovereign though it was in law; and they demand the progressive eradication of such conditions of influence. Further, they insist that colonial status involves the imposition of decisions by one people upon another, regardless of whether the territory inhabited by the subject people has been formally annexed or not.

Independent observers prefer a third definition. A colony is any territory in which the conditions of life—social, economic, political—are defined in considerable measure for the whole population by a minority different from the local majority in culture, history, beliefs and often race. This definition would include the bulk of the territories considered legally as colonies but would exclude some of the more sweeping claims of anticolonists. It covers the relationships established by the Soviet Union over central Asia and the Baltic littoral, by Nazi Germany over the bulk of Europe during World War II and by Japan over east Asia between 1931 and 1945.

**History.**—The establishment of colonies is as old as the recorded political history of man. Ancient Egyptian, Persian, Indian, Greek and Roman conquests usually involved the establishment of colonial relationships with the conquered, though the forms and intensity differed considerably. Later, Arab, Mongol and Chinese expansion into neighbouring countries had similar results. The period of western colonialism had its origins with the European Renaissance, the development of modern science, the great voyages of discovery and the concurrent existence in Spain, Portugal, England and France of soldiers, nobles, priests and merchants eager for foreign action, trade and missionary efforts. The period began about 1450 and reached its climax around 1900, when the last independent nonwestern territories were parceled out. Following World War I the reverse process of developing colonial resentment and desire for independence manifested itself in the growth of nationalism in Africa and Asia, with the result that colonial empires shrank rapidly.

However, even before the climax was reached, important changes occurred in colonial relations. The European powers fought many wars among themselves for trading monopolies with colonies and for the staking out of exclusive claims. When the Industrial Revolution overtook Europe after 1800, the technological advantage of the west made colonial conquest and rule in Africa and Asia much simpler, and it added the desire for markets, sources of raw materials and investment outlets to the previous motives for expansion. Between 1770 and 1820 certain colonies settled largely by emigrants from Europe grew increasingly impatient with government imposed from the mother country and successfully revolted; this resulted in the independence of the United States and of the Latin-American countries, and incidentally the virtual end of the Spanish colonial empire, and removed most of the western hemisphere from direct European control. British statesmen during the 19th century profited from the lesson and adopted a policy of granting self-government and independence to all European-settled colonies as rapidly as practicable. Thus Canada, Australia, New Zealand and the Union of South Africa by 1926 had evolved from colonial status, via full internal self-government, to complete sovereignty. At the same time they consented to accept the ruling monarch of Britain as their own and to remain closely allied militarily and commercially with the other country. Thus was

born the Commonwealth of Nations, a voluntary association of independent countries formerly colonies of Britain and unwilling to sever the imperial tie entirely. (See also COMMONWEALTH OF NATIONS.)

**Colonial Policies.**—*Great Britain.*—The hope of persuading its restive non-European colonial subjects to remain affiliated with Britain through the commonwealth at mid-20th century dominated British colonial policy. Long-range aims of policy included: (1) education designed to train a class of native leaders capable of manning the institutions of self-government and a modern economy; (2) economic development and foreign investment to raise living standards and to develop agricultural, mining and simple industrial facilities sufficient to assure the colony an income from world markets when it achieved independence; and (3) the gradual introduction of political self-government, progressing from self-rule at the village and district level to the creation of colonial legislatures with elected majorities and increasing autonomous powers, and ending with the choice of a native cabinet from among the freely elected parliamentarians. At that stage independence has been attained; the former colony is free to decide whether to remain in the commonwealth; thus Burma and Ireland declined, others accepted. Britain sought to export its values and institutions but permitted native groups to adapt these to their needs as they saw fit. Colonial reforms were sometimes hastened by unrest in the colonies and by pressures from the United Nations.

*France.*—French practice was different. For many years France denied the possibility of adaptation and autonomous development for its colonies and insisted on the full assimilation of colonial inhabitants and their territory into the French cultural and political system. There was no local self-government. Administration was controlled centrally from Paris, and educational policy was designed to train a small elite of colonial subjects as good Frenchmen. After 1945, however, "assimilation" as a goal gave way to "association." France in the period following World War II conceded full independence to Indochina, Morocco and Tunisia, though the concession came about only as a result of war or the threat of it. France also admitted that more extensive self-government within the federal French union was desirable and accordingly widened the franchise in colonies, reduced the privileges of French-identified natives and increased local legislative and executive powers. Wishing to avoid full independence for its remaining colonies, France preferred a federal tie through colonial and metropolitan representation in the purely advisory organs of the French union, special military and economic ties with Morocco and Tunisia and the closest possible relations with Algeria. As in the case of Britain, the severest cases of colonial conflict occurred when the metropolitan government sought to mediate between nationally self-conscious natives and sizable groups of European immigrants unwilling to adjust to African nationalism.

The constitution of the fifth republic of France, promulgated Oct. 4, 1958, provided for self-determination on the part of Overseas Territories. Of the 18 existing at the time only Guinea chose complete independence with no association with France. Five voted to remain as Overseas Territories and the remaining 12 (all African) voted to become autonomous republics within the new French Community. These, while continuing their association with France through the community, became independent by the end of 1960. (See also FRENCH COMMUNITY.)

*Others.*—Portugal insisted that its colonies were provinces of the mother country and in no sense subordinate to it; it maintained intact a doctrine and policy of assimilation characterized by little education, economic development or political evolution. Belgium fostered the rapid industrial and commercial development of the Congo but did not begin a process of technical and political education for the native population until some five years before independence was granted in 1960. The United States contemplated that its principal possessions should either be admitted to the union (as occurred with Alaska and Hawaii in 1959) or achieve self-government accompanied by commercial, military and foreign policy links with Washington (Puerto Rico). For its Pacific ocean possessions and trust territories, on the other hand, the United States had no plans for independence. As for the So-

viet Union, it denied having colonies and insisted that culturally non-Slav areas were freely federated with the totality. Its policy in central Asia combined systematic communization of tribal and Islamic socioeconomic institutions with a shifting policy of encouraging, alternately, local cultural autonomy and russification.

Soviet control in eastern Europe is not usually so exercised as to make these countries fall under this definition of colony.

**International Supervision.**—With the establishment of the United Nations, colonial policy was declared a matter of interest to the entire world; concurrently the term nonself-governing territory was substituted for colony in official discussion. In the case of the former Italian colonies in Africa, for instance, the United Nations itself decided on the independence of Libya and Somalia and the federation of Eritrea with Ethiopia; it subsequently supervised the political and economic development of those countries to full nationhood. According to the United Nations charter, colonial powers must administer all their possessions so as to stress the progress of the indigenous population. Further, they must report annually to the general assembly on steps taken to implement the obligation. The duty to report gradually was extended as a result of pressures of the anticolonial nations to include the submission of information not initially required and even the hearing by the general assembly of petitioners from the colonies.

The UN charter permitted the voluntary placing of territories under the trusteeship system (*q.v.*), by which the administering country promised, in terms of specific agreements, to advance the colony to self-government or independence, to administer it in accordance with internationally defined standards, to permit visiting United Nations missions to inspect progress, to report annually and to submit to questioning and to grant colonial subjects the right to petition the UN. Seven colonies in Africa and four in the Pacific ocean, with an aggregate population of about 20,000,000, were at one time under the system. Several subsequently achieved independence or joined neighbouring colonies that had attained statehood, in all cases under close UN supervision. However, no colonial power by the early 1960s had voluntarily placed under the trusteeship system any colony that had not been previously seized from another colonial power as a result of war, and it had not proved possible to extend the system to other tension areas.

There can be no doubt that the United Nations supervisory system, articulated by the majority of anticolonial nations even when specific recommendations of the United Nations were ignored, spurred steps toward colonial self-government and independence by France, Britain, Belgium and the United States. See EMPIRE; IMPERIALISM; MANDATE; UNITED NATIONS; see also references under "Colony" in the Index volume.

**COLOPHON**, an ancient city of Ionia, situated inland about 15 mi. N.W. of Ephesus. Its port was at Notium. The site lies near Degirmendere. Excavation of the ancient city (by the American School of Classical Studies at Athens and the Fogg Art museum, Harvard university) began in 1922. Colophon was a very flourishing city in the 8th and 7th centuries B.C., a great period of Ionian commercial enterprise. It was the mother city of Smyrna; it was ruled by a timocracy; and it provided a famous troop of cavalry. It was famous for its luxury, imitated from the Lydians. It claimed to have produced Homer, but its greatest genuine literary names were Xenophanes and Antimachus (*qq.v.*).

The first shock to its prosperity was the assault by Gyges of Lydia c. 665 B.C. Lysimachus, one of Alexander the Great's generals, transferred the population to his new city at Ephesus; but the Colophonians returned after his death in 281 B.C. Subsequently the old city declined in favour of Notium (New Colophon). Near Notium was the important shrine of the Clarian Apollo, whose temple and oracle were being excavated in the early 1960s.

See *Art and Archaeology*, vol. xiv, pp. 256–260 (1922); *American Journal of Archaeology*, 2nd series, vol. 27, pp. 67–68 (1923).

**COLOPHON**, a final paragraph giving particulars of title, authorship and other matters, sometimes found, from the 6th century onward, in medieval and Renaissance manuscript texts, and frequently in early printed books. In manuscripts a colophon was occasionally added by the scribe, giving his name, the date and place of completion of the work and a pious expression of thanksgiving for the end of his task. In printed books the author's colophon, when present, is sometimes separate from, and sometimes incorporated in, the printer's colophon, which may give some or all of the following information: the date and place of printing, the names of the printer and, when applicable, of his partner, financial backer, patron, publisher, editor or proofreader, and other circumstances connected with the printing of the work. At its fullest the colophon thus gives considerably more information than the title page which later took its place; moreover, although first found in a printed book in 1463, the title page is infrequent before the 1490s and does not normally replace the colophon until after 1520. The colophon is therefore one of the chief primary sources of information, not only for the printing of individual books, but for the whole history of early printing. Its lack is felt in those 15th-century books (approximately one-third) which do not contain a colophon, and which must therefore be laboriously assigned to printer, place and date by examination of their type.

The first printed colophon, which also contains the first printed date of completion, occurs in the 1457 Psalter produced by J. Fust and P. Schöffer at Mainz:

The present copy of the Psalms, adorned with beauty of capital letters and sufficiently picked out with rubrics, has thus been fashioned by an ingenious method of printing and stamping without any driving of the pen, and to the worship of God has been diligently completed by Johannes Fust, citizen of Mainz, and Peter Schoeffer of Gernsheim, in the year of the Lord 1457 on the Vigil of the Assumption [i.e., Aug. 14].

The use of the colophon has often been revived in modern times, for the sake of its convenience, pleasant appearance and historical links with the golden age of early printing, by fine printers such as William Morris at the Kelmscott press and C. H. St. John Hornby at the Ashendene press. The word colophon is borrowed from the Greek for "a summit," and hence came to mean a finishing touch. It is first used in English in the latter sense in Robert Burton's *Anatomy of Melancholy* (1621), and with its full bibliographical meaning by Joseph Ames in his *Typographical Antiquities*, p. 20 (1749).

See A. W. Pollard, *An Essay on Colophons* (1905); R. S. Grannis, "Colophons," in *The Colophon*, part 1 (1930). (G. D. P.)

**COLORADO**, a tribe of South American Indians, so named because of the unusual amount of red paint (Spanish, *colorado*, "red") with which they decorated their bodies.

Although traditions depict the highlands as their original home, their way of life indicates a long period of adjustment to their present habitat, the lowland tropical forests of northwestern Ecuador. Deriving their subsistence from agriculture and from hunting and fishing, they devote considerable effort to collecting forest products which are traded for steel tools and other manufactured goods.

There are no true villages, and although there is some economic co-operation among neighbouring families, in most respects the inhabitants of the scattered homesteads are independent of one another. Converted to Christianity at an early date, the Colorado practise many Roman Catholic rituals. However, they also believe that disease is due to witchcraft, and treatment is based on magical procedures.

See John Murra, "The Cayapa and Colorado," *Handbook of South*

*American Indians*, ed. by Julian H. Steward, Bureau of American Ethnology, Bulletin 143, vol. 4, pp. 277–291 (1948). (Se. L.)

**COLORADO**, known as the "Centennial state" because of its entrance into the union in 1876, 100 years after the signing of the Declaration of Independence, a state of the United States, is bounded on the north by Wyoming and Nebraska, on the east by Nebraska and Kansas, on the south by Oklahoma and New Mexico and on the west by Utah. It is the 8th largest state, having an area of 104,247 sq.mi., and was the 38th state admitted to the union. The state capital is Denver. The state flower is the Rocky mountain columbine; the state tree, the Colorado blue spruce; and the state bird, the lark bunting. The state motto is *Nil Sine Numine* ("Nothing Without the Deity").

## PHYSICAL GEOGRAPHY

**Physiography.**—Colorado, which is situated between approximately 37° and 41° N. lat. and 102° 3' and 109° 3' W. long., consists of three topographic zones—mountains, plains and plateaus. The mountains are the dominating feature of the state. They gather the snows to feed the rivers that irrigate the land, and they hold the gold and silver veins that attracted the first settlers; their majestic beauty draws thousands of visitors to the state annually. Fifty-five named peaks rise above 14,000 ft., and more than 1,000 reach above 10,000 ft. The mean elevation of the state is 6,800 ft. The mountain zone, running north and south through the middle of the state, is a complex system of ranges and cross spurs. The Front range, running from Wyoming to Pikes peak, continues to New Mexico as the Sangre de Cristo (Blood of Christ) range. Longs peak (14,256 ft.), Mt. Evans (14,264 ft.), Pikes peak (14,110 ft.) and Blanca peak (14,317 ft.) are outstanding along this chain. West of the Front range is the Park range, extending from near Wyoming to the head of the Arkansas river. West of the upper Arkansas is the Sawatch range, containing Mt. Elbert, the highest peak in the state (14,431 ft.), and the Collegiate range—Mts. Harvard (14,420 ft.), Yale (14,196 ft.), Columbia (14,073 ft.), Princeton (14,197 ft.) and Oxford (14,153 ft.). West of the Sawatch range are the Elk mountains, from which rise Maroon (14,156 ft.) and Snowmass (14,092 ft.) peaks. The San Juan mountains are a massive rugged group in the southwest portion of the state. They contain many high and precipitous peaks, among which are Uncompahgre (14,309 ft.), Sneffels (14,150 ft.) and Wilson (14,246 ft.). (See also ROCKY MOUNTAINS.)

The plains stretch eastward from the base of the Rocky mountains. This region was for centuries a treeless, grass-covered area, dotted here and there with isolated buttes and ribboned with the white sandy beds of intermittent streams. The shallow valleys of the Platte and the Arkansas rivers, and the low divide between them, are the most prominent features. The region is a part of the land once known as the "great American desert," inhabited by vast herds of bison and tribes of nomad Indians. By mid-20th century, however, six lines of railroads and hundreds of miles of excellent highways crossed the region; thin threads of irrigation ditches wound out from the river channels onto the uplands, enclosing irrigated areas rich with sugar beets and alfalfa; and scientific dry farming had made a checkerboard of the wheatfields and cornfields on large areas of the high plains.

The plateau region of western Colorado consists of a series of mesas or plateaus that decline gradually toward the western border of the state. The White River, Yampa, Roan and Uncompahgre plateaus, the Grand and the Battlement mesas and the Danforth hills are the most notable elevations. Cut by numerous deep valleys and canyons, the plateau country has a comparatively small area suitable for agriculture, but the broader valleys are peculiarly adapted to fruit growing, and horticulture ranks high among the industries of the region. Large areas of stratified plateau consist of vast oil-shale deposits, portions of which have been set aside as an oil reserve for the needs of the U.S. navy.

Colorado is called the mother of rivers. From the snowbanks of the continental divide, great streams radiate like the spokes of a wheel. One system of streams ultimately reaches the Mississippi river, another courses southward through the Rio Grande to the Gulf of Mexico, while a third flows westward through the

Colorado to the waters of the Pacific. The principal rivers of the eastern slope are the North Platte, South Platte and Arkansas; those of the western slope are the Colorado and Green and their tributaries—the Yampa, White, Gunnison, Dolores and San Juan. All of these streams, in the mountainous region near their sources, have cut deep and rugged canyons through upland ranges and spurs. The Royal gorge of the Arkansas river is spanned by one of the highest suspension bridges in the world. The Black canyon of the Gunnison river, Gore canyon, Yampa canyon and others are equally majestic. Although the rivers are not navigable, they have determined the routes of land transportation, the areas of irrigated agriculture and the location of cities and towns.

**Climate.**—Colorado is noted for its climate and atmosphere. The normal atmospheric pressure in Denver, at 5,280-ft. elevation, is 12.2 lb. per square inch, considerably lower than average for the U.S. The average annual humidity there, at noon, is 38%. There is a wide variation in the normal monthly and annual mean temperatures in different parts of the state because of the altitude. Through a 62-year period Colorado's mean temperature was 45.2° F.; the highest was 115° and the lowest —54°. Winter temperatures are usually mild, with extreme cold seldom lasting more than a few days.

Colorado is a semiarid state, the average precipitation being about 17 in.; but there is a wide variation, 7 to 60 in., in different sections. The winter snowfall varies almost directly with the altitude, five times more snow falling on the 14,000-ft. peaks than on the 5,000-ft. plains. There are active glaciers and permanent snow beds in the north central part of the state. As a result of the high altitude and low humidity, there is a great range of temperature. In summer there is a marked difference between the temperatures in the sun and in the shade; the nights are always cool.

**Plant and Animal Life.**—The great differences of altitude have caused wide variations in vegetation and animal life. In the high mountains are plant species typical of the far north; in the arid south and southwest, desert types exist. Variations of life types, caused by altitude, are especially noticeable in the belts of trees at various elevations in Colorado mountains—from the cottonwoods on the plains, through the yellow pine, aspens and Engelmann spruce, up to the treeless region above timber line. Animal life is not completely stratified, but it shows considerable variations with the elevation.

Buffalo and beaver are animals that particularly affected the history of the region. Until replaced by range cattle, the American buffalo (bison) provided the food supply for the Indians and meat for early settlers. The beaver attracted the trappers who became the first explorers of the region. Deer have continued from the beginning as important game animals; fish also lure sportsmen.

**Parks and Monuments.**—There are two national parks and six national monuments in Colorado. The Rocky Mountain National park (*q.v.*) contains a 35-mi. chain of giant peaks within its 259,200-ac. expanse. More than 350 cliff dwellings, 400 mesa-top pueblos and several hundred pit dwellings are included within the more than 52,000 ac. of Mesa Verde National park (*q.v.*). The remains of prehistoric dwellings are preserved in Hovenweep and Yucca House National monuments. Colorado National monument, a 17,500-ac. area, contains beautiful canyons, monoliths, petrified woods and prehistoric remains. Rich fossil beds have been preserved in Dinosaur National monument (*q.v.*).

More than 51,000 ac. of sand dunes were incorporated in the Great Sand Dunes National monument, and the spectacular Black canyon on the Gunnison river was placed under the administration of the national park service in Black Canyon of the Gunnison National monument. Two former national monuments, Wheeler and Holy Cross, were incorporated in national forests.

The national forests, embracing most of the mountain region, cover one-fifth of the state.

## HISTORY

Colorado was acquired by the United States in three successive waves of westward expansion. The portion north of the Arkansas river and east of the meridian of its head was acquired by the Louisiana Purchase (*q.v.*) in 1803, but its exact boundary was not

established until 1819, when the western boundary of the United States was incorporated in the treaty with Spain. The boundary of the United States was extended farther westward in 1845, with the admission of Texas. By a boundary adjustment between that state and the federal government in 1850, a strip of territory between the Rio Grande and the present boundaries of Texas became a part of the public domain. The territory west of the Rio Grande was included in the Mexican cession of 1848.

**Prehistory and Exploration.**—Before the arrival of the first explorers Pueblo Indians lived in southwestern Colorado, and impressive ruins of their communal houses (originally constructed within the caves by their predecessors, the Basket Makers, as early as 500 B.C.) are preserved in Mesa Verde National park and adjacent areas. When the first white men arrived from Mexico, nomad Indians occupied the land: Cheyennes and Arapahoes roamed the region east of the mountains and Utes inhabited the mountain and plateau areas. (See also INDIAN, NORTH AMERICAN: *Culture Provinces: The Southwest.*)

Francisco de Coronado appears to have touched the southeast corner of Colorado on the return journey of an expedition (1540-42) that pushed as far as Kansas vainly seeking the fabled Seven Cities of Cibola. Failure to find treasure checked exploration for a time but after Juan de Oñate started a colony in New Mexico in 1598 occasional prospectors and herders entered the Colorado region. More than a century later (1706) Juan de Ulibarri pursued runaway Indians into eastern Colorado and took formal possession of the country for the king of Spain. The Silvestre de Escalante-Francisco Dominguez expedition, seeking a route to northern California, first explored western Colorado in 1776. It was the fur trade that took the first American, James Purcell, into the Colorado region in 1803. In 1806 Lieut. Zebulon M. Pike followed the Arkansas river into Colorado, incidentally sighting the famous peak that bears his name. Maj. S. H. Long led a government expedition up the Platte river and to the Rockies in 1820. Unimpressed with the high plains country, he labeled it the "Great American desert."

Other official expeditions, led by Henry Dodge (1782-1867), Lieut. John C. Frémont (*q.v.*) and Capt. John Gunnison (1812-53), explored the region. Even more important pathfinders, perhaps, were the trappers and traders. Kit Carson, Jim Bridger, Tom Fitzpatrick and their daring companions first thoroughly learned the geography of Colorado. But the development of the Colorado region was slow until the discovery of gold in 1858. From 1804 to 1854 the whole or parts of Colorado were included, nominally, in about six territories carved successively out of the trans-Mississippi country; but not one of these had any practical significance for an uninhabited land. In the 1830s fortified trading posts were established in the region. Named for their founders, these adobe posts—Ft. Bent, Ft. Lupton, Ft. Vasquez and Ft. Robidoux—were the first white habitations in Colorado. Then in 1846-47 the Mormons settled temporarily at the old Mexican town of Pueblo. Frémont had explored the region in 1842-43 and 1845 (and unofficially in later years for railway routes), and gave more trustworthy reports of the country than had his predecessors. Commerce in these years centred in the (New) Mexican town of Taos. Upon some Mexican land grants in southern Colorado the beginnings of permanent settlement were made; San Luis in 1851 was the first.

**From the Gold Rush to Statehood.**—A party of Cherokees on their way to California found a little gold near the site of Denver in 1850; but not until the coming of a large prospecting party in 1858 did real development begin. The company, led by Green Russell of Georgia, discovered the first paying placer; and news of this caused the gold rush of 1858. At first there was grave disappointment among the gold seekers, but on May 6, 1859, John H. Gregory found the first gold-bearing vein. Julesburg, in the extreme northeast corner, at the intersection of the Platte valley and the overland wagon route, became transiently important during the rush of settlers that followed. Emigration from the east was stimulated by the panic and hard times following 1857. During 1860-62 there was a continuous stream of immigration. Denver (under its present name), Black Hawk, Golden, Central City, Mount Vernon and Nevadaville were all founded in 1859; Breckenridge, Em-

## SCENES IN THE COLORADO ROCKY MOUNTAINS

1. Mountain stream in Lake county, bordered by aspen and pine trees, typical of Colorado mountain scenery
2. The columbine, adopted in 1899 as the state flower of Colorado. It is found in profusion at elevations of 6,000 ft. and higher
3. Pikes Peak in the Front range of the Rocky mountains, El Paso county; the elevation is 14,110 ft.
4. Sandstone spires in the Garden of the Gods, near Colorado Springs, 70 mi.

5. Hereford cattle grazing on a mountain range near Aspen
6. Estes Park village (foreground) at the east gateway to Rocky Mountain National park. In the background are the snow-capped peaks of the continental divide

Union stockyards at Denver, the largest sheep market in the U.S., and one of the largest cattle markets

Mining molybdenite at Climax, the world's principal producing source of this mineral which yields the element molybdenum, used in steel and iron alloys

Stockpiling gilsonite at refinery after receiving it through pipeline from mine. Gilsonite is a solid—an asphaltite—which yields high grade coke and gasoline when refined. The mines are on the Colorado-Utah border

Stacks of wheat on Colorado prairie lands, with the Rocky mountains in the background. Wheat is the chief agricultural crop of the state

#### ASPECTS OF THE ECONOMY OF COLORADO

pire, Gold Hill, Georgetown and Mill City were founded in 1860 and 1861.

The political development of the next few years was complicated. "Arapahoe county," including eastern Colorado, was organized as a part of Kansas territory in 1858, but a delegate was also sent to congress to work for the admission of an independent territory (later called Jefferson). The next year a movement for statehood was inaugurated, a constitution being framed and submitted to the people, who rejected it, adopting later in the year a constitution of territorial government. Accordingly the territory of Jefferson arose, claiming to extend over 6° of latitude (37°-43°) and 8° of longitude (102°-110°). There was the Kansas territorial government also, under which a full county organization was maintained.

Finally claims clubs and miners' and peoples' courts, organized by the pioneers and acting wholly without reference to Kansas, and with little reference to the local "provisional" legislature, secured justice in the mining country. Finally the U.S. congress established the Colorado territory, Feb. 28, 1861. Abraham Lincoln appointed William Gilpin as the first governor and the first legislature divided the territory into 17 counties, enacted civil and criminal codes and passed needed legislation. Colorado City, the first capital, was replaced by Golden in 1862. In 1867 Denver was made the temporary seat of government (in 1881 permanently, by vote of the people).

During the 1860s the development of Colorado was slow. The American Civil War drew men away; the deepening mines encountered refractory ores and a mining slump occurred. In 1862 some Texas forces were defeated by Colorado forces in an attempt to occupy the territory for the Confederacy. From 1864 to 1870 there was trouble with the Cheyenne and Arapaho Indians and a general Indian war threatened the settlements. An attack by federal troops on an Indian camp in Kiowa county in 1864 became known as the Sand Creek massacre. This was the darkest period in the state's history. In the 1870s conditions rapidly improved. The Indians were removed; successful smelting of refractory ores was devised; the first railroads came (1870); farming increased; and agricultural colony towns were founded. New mining regions were opened in the San Juan area and at Leadville, and the population increased nearly fivefold in the decade.

By 1867 the Republican party had prepared for the admission of Colorado as a state, but the enabling act was vetoed by Pres. Andrew Johnson. Finally, under a congressional enabling act of March 3, 1875, a constitution was framed by a convention at Denver (Dec. 20, 1875 to March 14, 1876) and adopted by the people July 1, 1876. The admission of Colorado to the union was thereupon proclaimed on Aug. 1, 1876.

In the 1880s the railroads were extended into the mountains and trunk lines were built. Dry farming was developed on the eastern plains. Iron production was begun at Pueblo and manufacturing plants were constructed in Denver. Most of the Utes were removed from the state in 1881 and the western slope was opened to settlement. Aspen was added to the mining areas. Then came the demonetization of silver with a resultant mining slump in all the silver-producing states in the 1890s and the nationwide panic of 1893. However, the discovery of gold at Cripple Creek in 1891 and the opening of a great mining camp there promised revived confidence and improved conditions.

**After Statehood.**—For a considerable time the history of the state was identified with that of its great mining camps. After 1890 industrial conditions were confused and development retarded by strikes and lockouts in the mines, particularly in 1893-94, 1896-97 and 1903-04, when martial law was several times necessary. Questions of railways, franchises, union wage scales and sheep and cattle interests entered into the political and economic troubles of these years. The Colorado labour wars were among the most important struggles between labour and capital, and afforded one of the most sensational episodes in the story of all labour troubles in the United States in those years. Following the repeal of the Sherman act in 1893 (see *BIMETALLISM*) the silver question became the dominant issue in politics, resulting in the success of the Populist-Democratic fusion party in three successive

elections and permanently and greatly altering prior party organizations. In the first half of the 20th century the two major parties became rather equally balanced in strength, control of the state administration alternating between the Republicans and the Democrats. In 1899 the cultivation of sugar beets, made practicable by extensive irrigation, was introduced and soon became an important agricultural occupation (see *Agriculture*, below).

The eastern plains of Colorado have been affected by periodic droughts. The severity of the drought of 1932-37 was such as to develop a large "Dust bowl" region and cause the abandonment of some areas. The introduction of the automobile caused a great transformation of social and economic life, brought in new services and added the important industry of highway construction. The mechanization of farming released labour from rural areas, while the growth of manufacturing, trade and the professions drew increasing population to the cities. World Wars I and II caused far-reaching transformations. The great depression of the 1930s affected every citizen by its widespread unemployment and the slump in trade and industry. The prosperous times at mid-20th century restored general prosperity to the state and its people. Denver especially experienced business expansion and booming real-estate growth, as it developed into a regional distributing point and business-management area and a headquarters of federal governmental agencies.

## GOVERNMENT

**Executive, Legislative and Judicial.**—The state constitution was adopted in 1876. The executive officials—governor, lieutenant governor, secretary of state, treasurer, auditor and attorney general—were to be elected for two-year terms. By constitutional amendment in 1959 the terms were extended to four years. The superintendent of public instruction was at first an elected political official, but in 1948 a constitutional amendment provided for the election of a five-member board of education to choose a nonpartisan commissioner of education.

The legislature is composed of two houses: the senate with 35 members elected for four-year terms; and the house of representatives of 65 members elected for two-year terms. In 1963 the house was reapportioned by population, and in 1964 the senate also was reapportioned on that basis; both houses were reapportioned again in 1965; and single-member districts were authorized by constitutional amendment in 1966. The four congressional districts also were reallocated by population in 1964. The legislature met biennially until 1951; thereafter annually. Women's suffrage was adopted in 1893. Initiative and referendum measures were added to the constitution in 1910.

The judicial department comprises a supreme court of seven members, elected for staggered terms of ten years, and district, county and justice courts.

**Finance and Taxation.**—After mid-20th century the state's annual receipts from all sources amounted to more than \$350,000,000. In addition, about \$60,000,000 annually came from the federal government. Principal sources of state revenue included taxes on property, sales, income (including corporate income), liquor, inheritances, gifts and motor fuel. The state's expenditures totaled more than \$350,000,000 annually, but the state had no bonded debt. In the 1960s approximately 35% of the state's revenues was spent on education, about 20% on highways, about 15% on public welfare and about 5% on health and hospitals. By the 1960s the state's income was about five times as great as it had been prior to World War II. Over the same period per capita income increased about 400%, and approached \$2,000, just below the national average.

## POPULATION

In 1860, the year before its incorporation as a territory, Colorado had a total population of 34,251, of which 86.1% was classified as rural. The population grew only slightly during the next decade, but from 1870 to 1880 (the first census after Colorado's admission as a state) it increased almost 500%. The total population was 194,327 in 1880, 68.6% rural and ranked 35th among the 38 states and territories that then comprised the union. By 1900

than 200,000 sec.-ft. Its water supply, with storage, is estimated to be equivalent to a uniform flow of 19,300 sec.-ft. at Lees Ferry, 22,600 sec.-ft. at the lower end of Black canyon and 21,100 sec.-ft. at Parker. When development in the upper basin is completed and the canyon section and the lower river are developed these quantities will be reduced. With an average annual flow at Yuma of 17,000,000 ac.-ft. and an average silt content of 0.62% by volume, the annual load of silt brought to the delta region by the Colorado and Gila averages 105,000 ac.-ft., or 170,000,000 cu.yd.

The region traversed by the Colorado and its tributaries was the home of the early Pueblo people of whom there is almost no record except the hieroglyphics on the rocks, the ruins of their irrigation systems, and the cliff dwellings by which they are most widely known; in this region were Spanish missions whose history extends back nearly to the days of Balboa and Cortez; there is the Grand canyon of the Colorado, whose grandeur cannot be described; and there is the extremely remote and the most spectacular system of natural bridges of the world.

For more than 1,000 mi. along its course the Colorado has cut a deep, narrow gorge or canyon, but at some points where lateral streams join it the canyon is broken and these narrow transverse valleys divide it into a series of canyons. Virgin, Kanab, Paria, Escalante, Fremont, San Rafael, Price and Duchesne rivers on the west and the Little Colorado, San Juan, Grand, White and Yampa on the east have also cut narrow, winding gorges or deep canyons. Each river entering these has cut another canyon; each lateral creek has cut a canyon; and each brook runs in a canyon; so that much of the upper part of the basin of the Colorado is traversed by a labyrinth of deep gorges. The longest unbroken trunk canyon through which the Colorado runs is the Grand canyon between the mouth of the Paria and the Grand Wash.

The Grand canyon is 218 mi. long and at one place is 15 mi. wide and nearly 6,000 ft. deep. All the scenic features of this canyon are on a grand scale. Low plateaus, dry and treeless, stretch back from the brink of the canyon. In some places the rock is composed of richly coloured and variegated marls, and there the surface is a bed of loose, disintegrated material through which one walks as though in a bed of ashes. In other places the rock is a soft sandstone, the disintegration of which has left broad stretches of drifting sand, white, golden and vermilion. Where this sandstone is a conglomerate, a paving of pebbles has been left—a mosaic of many colours, polished by the drifting sands.

On the California side of the lower portion of the river in the United States a vast desert, known as the Colorado desert or the Salton basin, stretches northwestward from the head of the Gulf of California, a distance of 150 mi. At one time the Gulf of California extended a long distance farther to the northwest, above the point where the Colorado now enters it, but this stream brought its mud from the mountains and hills above and bore it into the gulf, across which it gradually erected a vast dam until the waters on the north were separated from those on the south. Then the Colorado cut a channel into the lower gulf. The upper waters, being cut off from the sea, gradually evaporated. The bottom of this ancient upper gulf has come to be known as the Salton sink. It is now land about 235 ft. below the level of the sea. On the Arizona side of the river there are similar desert plains, but these are interrupted by mountains.

In the year 1905 there occurred, about 3 mi. below the California-Mexico line, a break which diverted all the waters of the Colorado into the Salton sink and created the Salton sea, with a maximum depth of 79 ft., a length of 50 mi. and a width of 10 mi. to 15 mi., a total water area of 300 sq.mi. The break threatened inundation of the entire Imperial valley (*q.v.*) and permanent blocking of the Southern Pacific route. Because of this latter danger the Southern Pacific company stopped the crevasse and completed, in 1907, a line of protective levees, a project involving a great deal of engineering skill and an outlay of \$2,000,000.

Under existing treaties neither the United States nor Mexico can take action along the common boundary line which might impede navigation on the Colorado river. The language of the treaties does not, however, appear to prevent the taking of water for navigation purposes from the Colorado in the United States

above the point where it forms the boundary line between the two countries.

The Colorado river is one of the remarkable rivers of the world in its value for irrigation and water power. It combines, in proper sequence for complete use, a large quantity of water, great concentrations of fall, reservoir sites for the control of flow, sites for power plants, and several million acres of irrigable land below the stretch where power may be developed. More than 5,000,000 prime horsepower can be developed. The flood menace is a serious one; the silt brought down annually to Yuma produces dangerous meandering in the leveed sections in the delta and causes the river to seek new outlets. These threats necessitate large expenditures for revetment and the steady raising of levees to prevent further disasters such as occurred in 1905.

For the purposes of controlling floods and regulating the flow of the lower Colorado river and for interception of silt, providing for storage and delivery of water for irrigation purposes and for the generation of power, congress provided for the construction of a dam in the Colorado river at Black canyon or Boulder canyon. As the project entailed an adjustment of the water rights claimed by Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, a commission comprised of representatives of each of these states and of the United States prepared, in 1922, a plan for the distribution of the waters, giving 7,500,000 ac.-ft. annually to the upper states (Colorado, New Mexico, Utah and Wyoming), and 7,500,000 to the lower states. A disagreement between Arizona and California delayed ratification of this compact until 1928 when all but Arizona ratified by agreeing to an amendment that the ratification of any six of the states would make it effective. Congress followed by passing the Boulder Canyon Project act on Dec. 21, 1928, and Pres. Herbert Hoover issued a proclamation the following June authorizing construction. Construction was not formally begun until Sept. 17, 1930, but the rapid completion of four huge diversion tunnels, each 56 ft. in diameter, during the next three years, providing a dry bed on which to construct the dam, and the erection of a city to house 600 workers high above the waters of the projected dam and the construction of 53 mi. of railway and 40 mi. of improved highway completed the early stages of the project and attracted national attention to that great engineering feat. The acceleration of public works projects under the Franklin D. Roosevelt administration speeded construction, and the dam was completed in 1936. It is 726 ft. high and contains 4,400,000 cu.yd. of concrete. Lake Mead, its man-made reservoir, is 119 mi. long and stores 31,047,000 ac.-ft. of water. The hydroelectric plant has an ultimate capacity of 1,344,800 kw., and the income from the sale of electric power is applied toward repayment of funds advanced by the federal government for construction. The project is operated by the bureau of reclamation under the provisions of the Boulder Canyon Project act of 1940; the power plant is operated by the city of Los Angeles and the Southern California-Edison company as agents of the United States under the supervision of the bureau of reclamation.

The project opened a new area for colonization provided with an adequate hydroelectric power supply and irrigation. Originally known as Hoover dam and then as Boulder dam, it was officially named Hoover dam in 1947. In 1956 a law was passed by congress authorizing the construction and operation of the following units, power plants and transmission facilities of the Upper Colorado river basin: Glen canyon, Flaming gorge, Navajo and Curecanti dams; with the Emery county, Central Utah, Florida, Hammond, La Barge, Lyman, Paonia, Pine river extension, Seedskaadee, Silt and Smith Fork as participating projects. See also GRAND CANYON.

See F. P. Farquhar, *Books of the Colorado River* [and] *the Grand Canyon* (1953); Frank Waters, *The Colorado*, "Rivers of America Series" (1946). (E. JA.; M. J. L.)

**COLORADO SPRINGS**, a city of Colorado, U.S., 75 mi. S of Denver, at the confluence of Monument and Fountain creeks; at the eastern base of Pikes Peak, it stands on a mesa 6,008 ft. above sea level. It is the seat of El Paso County. Pop. (1960) 70,194; standard metropolitan statistical area (El Paso County)

143,742. (For comparative population figures see table in COLORADO: *Population*.)

Colorado Springs is one of the most popular tourist centres of the Rocky Mountains because of its fine climate and its many scenic attractions. It is also a military centre of great importance. The North American Air Defense Command has headquarters at Ent Air Force Base in Colorado Springs. Fort Carson (established 1942, made permanent 1954) is situated on a 60,000-ac. reservation 5 mi. S and the U.S. Air Force Academy (authorized 1954, occupied 1958) is located on a 17,800-ac. reservation 10 mi. N of the city.

The Colorado College, a private, nonsectarian, coeducational school of liberal arts, was established in 1874. Its enrollment is drawn from all parts of the U.S. Another cultural influence in the community is the Colorado Springs Fine Arts Centre (established 1936). Still other institutions are the Colorado School for the Deaf and Blind, the International Union Printers Home, and the Myron Stratton Home, founded by the will of the Cripple Creek gold miner, W. S. Stratton.

Manitou Springs, 6 mi. W, is a summer resort and the site of famous mineral springs. Between the two cities lies the Garden of the Gods, well known for its fantastic outcroppings of bright-coloured sandstone and forming a part of the 3,164-ac. city park system. Other points of scenic interest include the North and the South Cheyenne canyons, the Cave of the Winds, and Pikes Peak. On nearby Cheyenne Mountain are the Mountain Zoological Gardens, established in 1921, and the Shrine of the Sun, a 100-ft. rose-pink granite tower dedicated as a memorial to Will Rogers on Sept. 5, 1937.

The site of Colorado Springs was favourably noted by many explorers and travelers long before settlement. The historic town of Colorado City, which sprang up during the 1859 gold rush, was consolidated with Colorado Springs in 1917. The latter was founded and laid out as a model city in 1871 by Gen. W. J. Palmer, president of the Denver and Rio Grande Railroad. It has had a city-manager form of government from 1921. The water supply was increased in 1953 by Blue River water brought by tunnel from the western slope of the continental divide. (Hy. L. C.)

**COLORATION, BIOLOGICAL.** The vast realm of colour in living forms has, from man's earliest days, incited his wonder and active curiosity. Aside from the universal aesthetic appeal of colour for mankind through the ages, pigmentation holds special attractions for all biologists. Moreover, chromatology (the study of colours) finds applications in medicine, agricultural science, numerous arts and industries, and certain military operations.

The physician is often aided in his diagnosis and treatment of diseases by following the visible signs of various metabolic processes as reflected by the colours of tissues and body fluids. The grower has long recognized seasons of ripening or reproductive maturity by viewing the changes in kind or intensity of pigmentation in his products. And the geneticist, pursuing colour expression in successive generations, is in reality studying heritable biochemical operations within the organism. The comparative metabolism of coloured molecules is indeed one of the important realms of investigation in the wide field of biochemistry.

This article deals with the range of colour throughout nature, and is divided into the following sections:

#### I. Animal Colours

##### A. Structural Colours (Schemochromes)

1. Reflection
2. Interference
3. Scattering and Diffraction

##### B. Pigments (Biochromes)

1. Chemistry and Physiology
2. Carotenoids
3. Naphthoquinones
4. Anthraquinones
5. Flavones
6. Tetrapyrroles
7. Melanins
8. Indigoid Derivatives
9. Purines and Pterins
10. Lyochromes (Flavins)
11. Miscellaneous Pigments

##### C. Function

1. Vision and Heat Regulation

2. Concealment
3. Warning
4. Recognition

#### II. Plant Colours

##### A. Plastid Pigments

1. Chlorophyll
2. Carotenoids

##### B. Vacuolar Pigments

1. Anthocyanins
2. Anthoxanthins
3. Chemical Relationships

### I. ANIMAL COLOURS.

Animals exhibit an extraordinary array of colours and colour patterns. The colours include not only reds, yellows, greens, and blues but also black, white, and grays. The colour patterns are closely related to the form, contours, and certain aspects of the habits of the animals.

The subject of animal coloration poses innumerable fascinating problems. These fall into two general categories. The first relates to the chemical nature of the pigments themselves, how the animal synthesizes or otherwise derives them, and the physical basis of the structural colours. The second relates to uses or functional values of the colours in the life of the animal.

Animal coloration is achieved in two entirely different ways: (1) chemically, by natural pigments (biochromes), coloured molecules which reflect and/or transmit visible light; and (2) physically, by colourless architectural structures (schemochromes), submicroscopic ridges, striations, facets, and layers which break up light rays into their component colours. Pigment colours are not substantially changed by physical methods such as grinding or crushing; structural colours, however, are altered and sometimes completely destroyed by such operations. If, for example, a blue feather of a jay is crushed, it appears black: the blue is a structural blue, resulting from the scattering of ordinary light by the delicate organization of a colourless horny subsurface layer; black pigment that lies beneath the scattering layer shows through when this layer is disrupted.

It will be well to consider briefly the schemochromic sources of coloration before discussing the biochromic or molecular origins of true pigmentation. While biochromy, being of molecular foundation, may find conspicuous expression quite independently of the presence of any special minute, optically effective structural units, the reverse is not quite true, for the schemochromic colours are greatly reinforced and intensified by the presence of pigment, whether in underlying or in superimposed strata or occurring within the colour-producing structural layers.

#### A. STRUCTURAL COLOURS (SCHEMOCHROMES)

The physical principles of total reflection, interference, scattering, and to some extent, diffraction, all familiar in the inanimate world, are encountered also among tissues and tissue products of animals.

**1. Reflection.**—Total reflection of light, imparting whiteness to animal structures, often arises from the separation of finely divided structural materials by air spaces just as whiteness is conferred upon snow. Examples of this are seen in white feathers, fur, and hair, and in the wings of certain butterflies. Secretions or deposits in animal tissues may also contribute to the whiteness of total scattered reflection, examples being colloiddally dispersed fatty or lipid materials, calcium carbonate in the skeletons of numerous mollusks, crustaceans, corals, echinoderms, and protozoans, silica in sponges, proteinaceous materials in various serous membranes, deposits of white pterins in the wings of pierid and other butterflies, and silvery aggregates of crystalline guanine or other purine materials (see below) in the covering of numerous invertebrates and in scales of fishes.

**2. Interference.**—Disintegration of white light into its spectral components occurs in animal structures chiefly through interference: the incident light penetrates and is reflected back through successive thin-layered films to give striking iridescence, even in diffuse light. Sir Isaac Newton discussed the principle as applying to soap bubbles and other thin films in his book *Opticks* (1704). The Lords Rayleigh, between 1919 and 1923, applied

#### STRUCTURAL COLOURS

Tyndall blues in skin about head and neck of turkey (top left) and in the feathers of a blue jay (bottom) are caused by striations and ridges scattering the reflected light. Blue colour in the wing of *Morpho* butterfly (top right) is caused by iridescent interference

FROM PHOTO RESEARCHERS, INC. (TOP LEFT) RUSS KIRKE; (TOP RIGHT) BRADLEY SMITH; (BOTTOM) STEPHEN COLLINS

Newton's principle to the manifestation of iridescence by various structures of numerous beetles and other animals.

Iridescent interference colours are common in certain animal structures, including: wing scales of *Morpho* and other butterflies; the brilliant rainbow hues observed in feathers of hummingbirds, peacocks, pheasants, etc.; wing covers of many beetles; the outer skin of reptiles; and nacreous surfaces of pearls and molluscan shells. The lustre of human or other mammalian hair and its iridescent appearance in direct sunlight is due to the same phenomenon, the light being reflected in its disintegrated components by minute transparent scales which surround each individual hair. Pure prismatic refraction of light in animals is probably rare and limited to cases where direct beams of light encounter certain microcrystalline deposits. Diffraction by natural gratings or regular fine parallel striations is not uncommon among certain insects, and is conspicuous only when a direct beam of light strikes such structures at an angle. Studies with the electron microscope have confirmed the presence of such natural diffraction gratings in the wing coverings (elytra) of certain iridescent beetles.

**3. Scattering and Diffraction.**—Also common in animals is the display of blue colours, arising less frequently from blue pigment than from the scattering of reflected light by finely dispersed colloidal systems above dark layers of melanin deposits. Examples of these structural, so-called Tyndall blues (after John Tyndall, the British physicist who discussed the general phenomenon in 1869) are very numerous. Blue eyes, in which the cloudy tissue of the iris overlies the dark membrane or uvea, may be simulated by placing disks of agar gel or dried collodion film upon a black

surface. The blue skin about the head and neck of turkeys, cassowaries, and other such birds, or upon the face, buttocks, and genital parts of certain primates, derives its colour from the scattering of blue to violet fractions of light by colloiddally dispersed materials within the tissue, overlying an absorbing layer of melanin in the dermis. The blues of feathers and of many fishes and reptiles could be added to the other examples of structural blue.

Two types of structural coloration may act in combination; e.g., diffraction and interference. In other instances, structural and pigmental layers are superimposed. Most of the greens found in the skins of fishes, amphibians, and reptiles do not arise from the presence of a green pigment (although there are exceptions to this), but are the result of the emergence of scattered blue light through an overlying layer of yellow pigment. Similarly, the purple hues seen between red and blue areas in the naked skin about the neck and face of cassowaries or turkeys, or in that over the buttocks or genital regions of certain baboons and other primates, are derived from the complementary colour effect of blue-scattering and red hemoglobin.

#### B. PIGMENTS (BIOCHROMES)

**1. Chemistry and Physiology.**—The visible range of light is selectively affected by reflection from or transmission through particles whose size or whose vibrational frequencies lie between 3,000 and 7,000 Å (angstrom units; 1 Å =  $10^{-8}$  or  $\frac{1}{100,000,000}$  cm.). Those physical structures in the biological world that may fractionate white light have already been mentioned: namely, very thin, finely spaced laminations, ridges, or striations, all yielding

spectral effects; and minute, colloiddally dispersed particles which scatter incident light, reflecting only the most refrangible rays; that is, blue and violet.

The colour of a chemical compound depends upon the selective absorption of light within definite wavelengths, the unabsorbed rays being reflected or transmitted to the eye. This capacity to absorb visible light is due, in turn, to varying kinds and degrees of chemical unsaturation in colour-carrying groups (chromophores) within the molecule. These areas of special molecular activity arise from reduction in the relative speed or frequency of motion of one or more pairs of the compound's many rapidly vibrating electrons. Indeed, sufficient modification in the speed of electronic vibration imparts to the entire molecule a degree of special vibratory motion or chemical resonance. This phenomenon, in the modern view, is the basis of colour manifestation.

If the molecular resonance involves short, rapid waves, the shorter visible light waves will be absorbed (*i.e.*, those of the violet and the blue spectral regions) and the compound will, therefore, appear yellow. Red substances, having slightly longer resonance values, similarly absorb light in the blue and green regions. Blue or green compounds result from cancellation of light in the red or orange realm. Black substances absorb all light equally and completely.

The colours of most chemical compounds are not of spectral purity but include all of the visible light excepting the absorbed fraction; the commonly observed colour of a substance depends upon the dominant wavelength or that of maximum transmission.

There is good ground for the view that colour and chemical reactivity, and hence the potential metabolic value of a pigment to an organism, are parallel expressions of the same underlying molecular property of unsaturation. This is a reason for the careful consideration of the physicochemical attributes of biochromes or pigments and for continued researches regarding their metabolic position in the living organism.

The more important pigments of animals may be arbitrarily grouped into classes whose molecules are without combined nitrogen and others which contain this element.

Of the nonnitrogenous pigments, by far the most important, conspicuous, and widely distributed, both in animals and plants, are the carotenoids or polyenes. Chromolipoids, naphthoquinones, anthraquinones, and flavones represent other nitrogen-free pigments which occur in animals, but these are limited in distribution, and little is known of their physiological attributes.

In the nitrogenous group are several pigments of most diverse chemical nature and metabolic position. The tetrapyrrolic pigments include both the porphyrin class, present in the blood of many animals, and the bile pigments, occurring in many secretions and excretory products; the dark melanins occur in skin, hair, and other parts and represent metabolic end products. Several purines, while usually white or silvery in appearance, are included as pigments because they contribute to the total colour of numerous lower animals; similarly the pterins, which are derivatives of pyrimidine, are frequently white, but may often be yellow or other colours; the lyochromes or flavins, detectable in the tissues of all or nearly all living organisms, are identified with certain important biocatalysts; finally, the indigoid derivatives, which are somewhat limited in distribution, are, like the melanins, purines, and pterins, end products of metabolism.

In the following treatment are outlined the chemical configuration, colour, source, and metabolic features (insofar as the latter are known) of some representative animal pigments.

**2. Carotenoids.**—This group of red, orange, or yellow pigments, whose number of known compounds is constantly increasing, is of almost universal distribution throughout the living world. Carotenoids are insoluble in water, but may be readily dissolved in alcohol, ether, chloroform, and various other organic fat solvents. They are crystalline and in solution usually exhibit two or three absorption bands (but in some cases only one), characteristically in the violet to blue, sometimes extending into the green region of the visible spectrum. They are readily bleached by light and by exposure to atmospheric oxygen, and are unstable also in the presence of mineral acids, their chloroform solutions giving blue coloration upon treatment with concentrated sulfuric acid.

These pigments occur in plant organisms ranging from bacteria, fungi, and algae, to the most highly evolved flowering forms. Animals from Protozoa to the highest mammals, including man, contain carotenoids, although the tissues and blood sera of a number of mammals are almost or entirely devoid of these pigments. The

livers of some of these species often yield carotenoids, and it is known that the animals depend upon a supply of  $\beta$ -carotene (see fig. 1) or its metabolic derivative, vitamin A. Carotenoids are relatively more concentrated in ovaries or eggs, some testes, liver (or liverlike analogue in invertebrates), skin, eyes, and milk. Carotenoid pigmentation may be seen in the legs, body fat, and eggs of domestic poultry; in similarly coloured wing covers of many insects; and in the milk fat of cattle. In some animals a high degree of specificity exists for the absorption of either the hydrocarbon (carotene) class or the oxygenated (alcoholic or xanthophyllic) type of carotenoid.

The horse, for example, absorbs through the intestine only carotenes, from green food containing an ample supply of both kinds of carotenoid. The hen, on the other hand, stores only members of the xanthophyll class; many fishes and marine invertebrates likewise store only xanthophyllic carotenoids, rejecting in the feces or otherwise totally disposing of the carotenes. Other animals, including the frog and man, assimilate and store both classes in depot fat.

FIG. 1.— $\beta$ -CAROTENE

Striking displays of carotenoids are found in the skins of many fishes, amphibians, and marine invertebrates, including sea stars and brittle stars, mollusks, sea squirts, crustaceans, anemones and corals, and many marine worms. The blue, green, gray, chocolate, violet, and near-black pigments of certain crustaceans, naked mollusks, and sea stars are in many instances due to carotenoids in chemical conjugation with protein. Denaturation of the protein by immersion of the specimen in boiling water or in alcohol frees the carotenoid involved and unmasks its colour; hence the familiar red colour of boiled lobsters. Marine animals commonly derive their rich supplies of carotenoids directly or indirectly from the countless microscopic plants or larger seaweeds. Even carnivorous fishes and flesh- or mud-eating invertebrates from the dark depths frequently exhibit rich pigmentation, derived from supplies of carotenoids long since generated in lighted waters above them.

A yellow condition of the skin known as xanthosis, carotenemia, or artificial jaundice, may follow excessive eating of carotenoid-rich foods, such as carrots or oranges. The condition, less common in adults than in children, is unaccompanied by pathological symptoms and disappears when excessive carotenoids are withheld from the diet. Hens and female fish mobilize body carotenoids to their eggs during laying (or spawning) season, with an evident loss of the yellow pigment from the skin. Males, however, may continue to exhibit the pigmentation. Derivatives of yellow carotenoids are responsible for the striking red colours observed in the exposed skin covering the legs and toes of the American flamingo (*Phoenicopterus ruber*), the leg joint of the Chilean species (*P. chilensis*), as well as for the pink colours in the plumage of flamingos, roseate spoonbills (*Ajaia ajaja*), and scarlet ibises (*Guara rubra*).

## BIOCHROMIC COLORATION

The naphthoquinone compound echinochrome is manifested in the purple colour of sea urchins, left. Carotenoid pigmentation is revealed in the red plumage and leg skin of flamingos

Captive animals of such species gradually lose their pigmentation, both from the skin, which fades, and through the seasonal feather molt, unless a generous supply of carotenoid material is included in the diet.

**3. Naphthoquinones.**—These compounds, occurring in many plants, are yellow, orange, red, and purple in colour. They are soluble in various organic solvents, and have found considerable use as dyes for fabrics. Their occurrence among animals was

FIG. 2.—ECHINOCHROME

long believed to be limited to the sea urchins and sand dollars (echinoids), whose spines, shells, and thin skin are often coloured red, purple, and, in some instances, green by echinochromes. (See fig. 2.) Some pigments of this class occur also in certain red crinoids or sea lilies. The skull, teeth, and other skeletal parts of the sea otter (*Enhydra lutris*) assume a pink to purple coloration as a consequence of the animals' having consumed, over some period of time, large numbers of sea urchins in their natural habitat. The echinochrome recoverable from the otter's skeleton is chemically similar to the compound obtained from its prey.

Echinochromes, like quinones generally, are mildly oxidizing and lose their colour when treated with chemical reducing agents. They assume different colours also according to the acidity or alkalinity of their surroundings. The purple colour of sea urchins is consistent with the faintly alkaline condition of the tissues and calcareous shell. The antihemorrhagic factor, vitamin K, is a naphthoquinone of yellow colour. Echinochrome is believed by some investigators to act as a respiratory stimulant for sea urchin eggs, to activate the spermatozoa of certain species of echinoids, and to attract the sperm to the eggs. Studies of crystalline melting point, absorption spectra, and other properties confirm the existence of a number of chemically different echinochrome compounds. The diverse coloration of various structures of some echinoid species is attributable to the presence of mixtures of several different echinochromes in varying proportions.

**4. Anthraquinones.**—A large number of brilliantly coloured compounds that have found wide application as dyes and chemical indicators of acidity or alkalinity are included in this group.

Like the naphthoquinones, with which they share a common chromophoric structure, they may be chemically reduced by certain substances.

Cochineal (*q.v.*) is the potassium salt of carminic acid, a red

FIG. 3.—CARMINIC ACID

pigment occurring within cells of the fat body of the female cochineal insect, a scale insect that lives upon certain cacti in Mexico and Central and South America. (See fig. 3.) Other species of scale insect store the same or a closely related pigment.

The dye is not confined exclusively to the fat body but is present also in the eggs and in cells of the larvae. It may constitute a considerable proportion of the weight of the adult female insect but is present in lesser amounts in the males.

Carminic acid, chemically extracted from the powdered insect material, imparts a permanent red colour to mordanted wool or silk. Cochineal, largely replaced by aniline dyes, is still applied, however, to the dyeing of certain fabrics, inks, and confections.

Kermesic acid, a red dye popular in ancient Greece and Rome, is extracted from the female kermes scale insect (*Coccus ilicis*), which thrives upon certain kinds of oak found in Spain, Portugal, and Morocco. Yellow-red in water, violet-red in acidic solutions, kermesic acid is employed as a dye, as is carminic acid to which it is chemically allied.

Laccaic acid is isolated from lac dye or lac-lac, the solid exudation or resinous secretion covering the female bodies of certain lac insects living on various plants of Southeast Asia (see LAC).

While these conspicuous anthraquinones are in all probability derived by the insects from the plants upon which they feed, no information is yet available as to the manner in which the compounds are metabolized, or concerning their possible physiological significance. Anthraquinone pigments have been discovered in red crinoids of the genus *Comatula*, notably *C. pectinata*, thus recalling the assimilation of certain related naphthoquinones by other sea lilies (see above).

**5. Flavones.**—These compounds occur in a wide variety of plants and in a few insects feeding upon such plants. They impart yellow colours to certain flowers. The chemical properties of

FIG. 4.—QUERCETIN

a yellow biochrome isolated from the wings of the butterfly *Melangaria galatea*, correspond closely with those of the plant pigment quercetin. (See fig. 4.)

Flavonoid pigments have been reported in the hypoderm of some strains of the larval silk moth (*Bombyx mori*) and in the cocoons of the Verdi strain. Early studies revealed similar pigments in the hypoderm of a number of true sucking bugs, including not only those parasitizing plants, such as the box elder bug (*Leptocoris trivittatus*) and the small milkweed bug (*Lygaeus kalmii*), but also the Philippine assassin bug (*Eulyes illustris*), which sucks the blood of other insects.

While most of the relatively few animals storing flavones derive the pigment directly from the plant hosts, the carnivorous forms,

such as the assassin bug, must obtain their flavones from preying upon herbivorous or perhaps omnivorous species.

The chemically related anthocyanins, the red, violet, and blue compounds often seen in blossoms, fruit, and leaves of plants, are occasionally encountered in larvae and adults of flies and true bugs. None of these classes of pigments has been shown to fulfill a particular physiological function in these animals, though they are believed to be involved in certain biochemical oxidations in the plants that synthesize them. (See also *Plant Colours: Vacuolar Pigments*, below.)

FIG. 5.—PORPHIN

**6. Tetrapyrroles.—Porphyrin Compounds.**—Porphin is the parent compound of the class of biologically important nitrogenous, water-soluble pigments called porphyrins. (See fig. 5.) They are represented in the green photosynthetic chlorophylls of plants and in animal hemoglobins (see *BLOOD: Blood Pigments*).

Heme lobins are present in the red blood cells of mammals, birds, reptiles, amphibians, and fishes, and in the circulatory fluids of many invertebrates, notably annelid worms and some arthropods, echinoderms, and mollusks. These compounds have the unique capacity to combine with atmospheric oxygen in lungs, gills, or other respiratory surfaces of the body, and to release it to the tissues. Hemoglobins are responsible for the pink to red colours observed in combs and wattles of birds and in the skin of man and other primates; particularly prominently coloured are portions of the face, buttocks, and genital regions of baboons. Hemoglobins are conspicuous also in the blood and muscles of many polychaete worms; they impart red or pink colours to the mouth musculature operating the radula or filelike rasping tongue of many marine snails, also to the mantle, foot, adductor muscle, brain, and gills of at least one bivalve—the common edible Pismo clam (*Tivela stultorum*). The sea cucumbers *Cucumaria miniata* and *Molpadia intermedia* carry hemoglobin in their red blood cells. The presence of hemoglobins has been recorded in species of *Daphnia* and other freshwater crustaceans; in certain aquatic insects, notably the midge *Chironomus riparius*; in the pond snail *Planorbis corneus*; and in the echiurid worm *Thalassema neptuni*. The hemoglobin content in certain *Daphnia* species varies, depending partly upon the aeration of the habitat, i.e., fading somewhat in aerated waters, but increasing conspicuously in redness in oxygen-poor waters. This ability to elaborate fresh hemoglobin under conditions of unfavourable oxygen supply suggests an important physiological adaptation toward survival. Similar conditions apply to the brine shrimp (*Artemia salina*).

Some parasitic animals seem to derive their supply of the blood pigment from their hosts. This applies to certain copepods that parasitize the gills of fishes and to nematode worms that infest swine and horses. Other examples are the larva of the botfly *Gastrophylus*, parasitic in the stomach of the horse, and the blood-sucking bug *Rhodnius prolixus*.

A singularly interesting discovery in the 1940s was that hemoglobin is present in the bacteria- (*Rhizobium*) harbouring root nodules of peas, beans, and other leguminous plants. It is believed that hemoglobin may, in this extraordinary instance, serve as a catalyst for the chemical fixation of atmospheric nitrogen, long known to occur within the root nodules. (See also *BACTERIA*.)

Other pigments chemically allied to the heme compounds are: cytochrome, the red oxidation enzyme which occurs in minute concentrations in nearly all cells; catalase, an enzyme of similar distribution which accelerates the breakdown of hydrogen peroxide; pinaglobin, a brown compound which serves as a respiratory aid in the mollusk *Pinna squamosa*; chlorocruorin, a green pigment

which plays a similar role in the blood of tube-building annelid worms; heliocorubin, a red compound encountered in the liver and gut of some snails; and actinohematin, responsible for some of the beautiful red colours of sea anemones. The physiological functions, if any, of the last two pigments have not been clarified.

Many invertebrates display porphyrin pigments, some showing fluorescence, in their skins or shells. The worm *Thalassema lankasteri*, like its relative *Bonellia*, possesses a bluish-green pigment in its skin and mucus. In acetone solution, the pigment is green and exhibits fluorescence in ultraviolet light; it resembles bonellin in chemical properties and in its absorption spectrum.

Like *Rhodnius*, certain parasitic worms presumably derive their characteristic porphyrin pigments from the heme of their vertebrate hosts. *Tetrathyridium*, a cestode parasite of the hedgehog; *Eustrongylus*, a red nematode in the dog; and *Taenia solium*, infesting the muscles of the pig, are believed to store porphyrin derivatives.

Uroporphyrin and conchoporphyrin have been recovered from the shells of many mollusks, and coloured oyster-pearls yield traces of free- and metalloporphyrins. Higher proportions of metalloporphyrins, apparently involving lead or zinc, in ratio to metal-

EDWARD VAN BAERLE, © ENCYCLOPEDIA BRITANNICA

Hartlaub's turaco owes the red colour in its wing feathers to turacin, a water-soluble copper salt of a uroporphyrin; the darker feathers contain an oxidized derivative of turacin.

free porphyrins, seem to apply to green pearls, whereas pink pearls have been found to possess both less total porphyrin and lesser proportions combined with metallic elements.

Various porphyrins occur in secretory and excretory products of animals, and some kinds, prominently so-called phorbides derived from plant chlorophylls, have been extracted from ancient natural deposits such as coal, petroleum, and muds from long-buried strata of the ocean floor. Oöporphyrin is responsible for the red flecks upon the eggshells of plovers and other birds. The remarkable African turaco (*g.v.*) secretes a copper salt of uroporphyrin III into its quill feathers. This red pigment (turacin) is readily leached from the feathers by water containing even traces of alkali, giving a magenta-red solution. Neutralization or mild acidification precipitates the pigment. The green plumes of the same bird owe their colour to the presence of turacoverdin, an oxidized derivative of turacin. There is some ground for the belief that in various lower animals certain porphyrins may be involved in activating pituitary hormones, including those concerned with the period of sexual heat.

**Bilins.**—Among the metabolic breakdown products of heme or allied pigments is a series of yellow, green, red, or brown nonmetal-

FIG. 6.—BILANE

FIG. 7.—CONVERSION OF TYROSINE TO MELANIN

lic tetrapyrroles typified by the simplest member, a colourless synthetic called bilane (see fig. 6). Small quantities of the red compound bilirubin ( $\text{C}_{33}\text{H}_{36}\text{O}_6\text{N}_4$ ), its green oxidation product biliverdin ( $\text{C}_{33}\text{H}_{34}\text{O}_6\text{N}_4$ ), and various other chemically homologous compounds occur in normal tissues and may be conspicuous in excretory and secretory materials under some circumstances. The bile pigments, though first identified in mammals, are by no means confined to them. Various members of the bilichrome series are encountered in invertebrates and among lower vertebrates.

Pterobilin is a blue pigment observed in the wings of many pierid butterflies and other insects, and their larvae exhibit or excrete allied compounds. Certain leeches, nourished by the blood of vertebrates, contain blue-green, red, or brown bile pigments in their blood, probably as a result of the breakdown of ingested hemoglobin. A violet bilichrome, haliotivolin, has been recovered from the shell of the abalone *Haliotis cracherodii*. Two related bilichromes, aplysioviolet and aplysiorhodin, occur in the purple ink of the sea slug *Aplysia punctata*. And the blue coral *Heliopora caerulea* yields a blue pigment, helioporphobilin.

Many fishes, notably among the needlefishes and sculpins (Cottidae), bear strikingly blue-green skeletons. The green pigment in the bones and scales of the needlefish *Belone belone* is closely related to or identical with biliverdin. The California needlefish (*Strongylura exilis*) likewise owes the blue-green colour of its skeleton to a very similar bile pigment and, among the mackerels and tunas (Scombridae), commercial catches of the skipjack *Katsuwonus pelamis* yield rare individuals whose endoskeletons, particularly the skull and vertebrae, are green or blue-green because of the presence of an insoluble salt of a pigment closely resembling biliverdin in its chemical and spectral properties. Contrary to the impression of some commercial dealers, the green colours persistent in the bones of some species do not reflect the presence of copper or another poisonous substance.

Oöcyan, a pigment responsible for the blue or blue-green colours in the eggshells of gulls and various other wild birds, is regarded by some as biliverdin. The dark-green pigment of the emu egg has been proved to involve biliverdin, accompanied by minor amounts of bilirubin.

PHOTOGRAPHED ESPECIALLY FOR ENCYCLOPEDIA BRITANNICA BY JAMES LARSEN

## BILICHROME COLORATION

Biliverdin and allied pigments in the dark-green shell of an emu egg

A green bilichrome once called uteroverdin, originating outside of the liver and found in hemorrhagic placental areas in dogs, is also biliverdin. The conspicuous yellow colour of horses' blood plasma arises in part from relatively high concentrations of bilirubin, which pertain after the animal fasts but which return to average values after it feeds.

Although the bilin pigments are in all probability derived largely from the metabolism of heme precursors, there is evidence that bilirubin, accompanied by iron salts, promotes the synthesis of new hemoglobin when injected into humans, dogs, or rabbits afflicted with secondary anemia.

**7. Melanins.**—Dark colours, indicating the presence of melanin pigment, are observed in feathers; in mammalian hair and eyes; in the skin and scales of numerous fishes, amphibians, and reptiles; in the ink of cephalopods; and in various tissues of invertebrates. Melanin is also found in skin moles of man and in black tumorous growths of many vertebrates. It is an end product of metabolism, formed as a result of oxidation and polymerization of tyrosine (see fig. 7) or similar phenolic compounds. This oxidation by dissolved atmospheric oxygen is catalyzed by a copper-containing enzyme, tyrosinase. Chemically reversible yellow, orange, or red stages in the successive oxidation are followed, if uninterrupted, by an intensely black end product.

Some white or albino animals may lack the power to elaborate either the enzyme tyrosinase in its active form or some intermediate compound necessary for pigmentation. Completely white or red variants of the sea anemone *Metridium senile*, for example, fail to develop melanin in their tissues as do brown variants of their species. But upon death or upon grinding of the tissues of such an albino animal, the macerated material blackens rapidly with the formation of melanin.

Pale yellow, tawny, buff, ruddy, brown, and black colours of hair are due to melanin in various phases of formation or in relatively finely divided condition. That dark, light-absorbing sublayers of melanin intensify structural blues or iridescent colours has been mentioned.

FROM HEWER IN "PROC. ROY. SOC. LONDON" (1923)

FIG. 8.—FROG MELANOPHORES

(A) expanded (skin is darkened green); (B) contracted (skin becomes pale)

Many fishes, lizards, amphibians, cephalopods (octopus, squid), and shrimps possess in their skin dark melanoid pigment in specialized cells called melanophores (fig. 8). Within the boundaries of these cells the pigment granules may become dispersed, making the skin dark, or may aggregate into a small mass at the centre, rendering the skin pale. (See fig. 9.) These pigmentary changes may be induced by certain chemicals or by physical stimuli; when alarmed, such animals often display colour changes adapted to concealment. In at least one of the crestfishes, *Lophotus*, much

FIG. 9.—DIAGRAM SHOWING SKIN OF TREE FROG DURING COLOUR CHANGE

As cells of component layers expand and distribute pigment, skin colour changes from (A) bright green to (B) dark green to (C) lemon yellow to (D) gray

melanin is stored within a special glandular sac, from which it may be expelled in forcible jets through a postanal opening by muscular contractions.

Black or brown melanins or melanoproteins are to be observed in many invertebrate animals. Certain of the worms, many crustaceans, and many classes of mollusks exhibit melanism in the skin. The red intermediate compound, formed during the transformation of tyrosine to melanin (see fig. 7) is hallachrome, which is encountered also in the marine worm *Halla parthenopaea*. It is green in alkaline solution. Hallachrome may be reversibly oxidized and reduced. Its original precursor may be either tyrosine or tryptophane.

Red or yellow uranidines, found in sponges, corals, jellyfishes, sea cucumbers, annelid worms, and tunicates, are believed to be chemically related to the melanins. Urochrome, the principal yellow pigment of urine, is considered to be a modified melanin. In certain diseases, melanin precursors cause urine to darken as oxidation occurs on standing (melanuria, alkaptonuria).

Black melanin recovered from the wool of hybrid Downs-Dorset sheep was originally assigned the empirical formula  $C_{105}H_{178}N_{23}SO_{38}$ , but there are variations in the elementary composition of melanins from different sources. They are extractable in very dilute alkali, soluble also, when fresh and undried, in very dilute acid solutions. Melanin, soluble in cold ethylene chlorhydrin, is bleached by such oxidants as hydrogen peroxide (which indeed is often applied to growing hair to create a blond effect), chlorine, chromate, or permanganate.

The degree of melanization depends upon relative concentrations of copper and of the copper-containing enzyme tyrosinase. Dark mammalian hairs contain higher traces of combined copper than do pale hairs. Minimal traces of copper are required for melanistic pigmentation of the hair (e.g., of rats); should the daily intake of copper fall substantially below the threshold value of a fraction of a milligram per animal per day, the new pelages emerge successively less dark.

In an individual strand of human hair, the cortex, beneath the outer layer of cuticular cells, surrounds the central medullary column or pith. Ellipsoidal or spherical microgranules of melanin are randomly distributed within the dried cortical cells, imparting pale-buff, brown, or black colours, depending upon relative numbers, sizes, and depth of hue of the individual microgranules. Melanin occurs in the medulla of some mammalian hairs; this medullary melanin may assume the status of a colloiddally dispersed stain rather than microscopically identifiable particles. Human red hair, unlike other hair, human or nonhuman, yields a unique iron-rich pigment. A similar substance has been obtained from red poultry feathers and is reminiscent of certain reddish melanin derivatives.

All human skin, except in albinos, contains greater or lesser amounts of melanin. In fair-skinned races the corium or deeply lying skin layer contains but little of the pigment, whereas in the darker races, dermal deposits of it are heavy and are fortified by numbers of smaller melanocytes in the upper skin layer or epidermis. Samples of human skin, photographed by electron microscopy have been found to contain minute particles of melanin pigment in the form of microspherules (0.2 to 0.3  $\mu$  in diameter) or rodlets (from 0.1  $\times$  0.4  $\mu$  to 0.18  $\times$  0.6  $\mu$ ). On exposure to sunlight, man's epidermis undergoes gradual tanning, or increase of melanin pigment, which helps to protect underlying tissues from injurious sunrays. (See also SKIN.)

FROM A. S. ROMER "THE VERTEBRATE STORY," THE UNIVERSITY OF CHICAGO PRESS

FIG. 10.—COLOUR CHANGE IN CATFISH PRODUCED BY DIFFERENT ENVIRONMENTS

(Above) fish taken from light container; (below) fish from dark container

Amphibians and fishes, maintained for protracted intervals upon black backgrounds, have been found to augment greatly the numbers of melanophores in the epidermis. Animals thus darkened gradually lose their integumentary melanin after transferral to containers with pale inner surfaces. (See fig. 10.)

There are some remarkable instances of rapid darkening of the skin through melanization. The relatively sudden appearance and rapid enlargement of black skin moles, actually malignant melanotic areolae, is well known. Among the fishes, the Tasmanian whitebait (*Lovettia sealii*) has been observed to exhibit rapid integumentary blackening upon entering the postspawning stage. There is a great increase in numbers of melanophores with successive stages of sexual ripeness, notably in the males; and individuals of both sexes, after spawning, show extensive darkened areas of the skin. In dying individuals the skin may become completely black.

In the very young downy chick of the American flamingo, the pudgy little legs are covered with delicate, naked skin, bright red or pink in colour due to the rich supplies of blood hemoglobin. It has been observed that the colour of the chick's leg skin deepens gradually, becoming black at the end of about the eighth day, when the chick is ready to leave its nest for the first time, no longer to be protected from direct sunlight by the hovering parents.

**8. Indigoid Derivatives.**—Like melanins, the indigo compounds are excretory products of certain animals, but in contrast to melanins, their distribution as pigmentary compounds is relatively limited. Unlike the dark, sombre melanins, many indigoids are red, green, blue, or purple.

*Indigo.*—Also called indigo-blue or indigotin, this occurs as a

FIG. 11.—INDIGO

glucoside in many plants of Asia, the East Indies, Africa, and South America. (See fig. 11.) It has long been used as a blue dye. While the pigment itself does not occur in the tissues of healthy animals, certain chemical derivatives of it are found in secretory and excretory products.

*Hallachrome.*—This red pigment in the epidermis of a marine worm has been discussed. The compound, as well as the chromogen of human melanuria, which is probably a derivative of 5, 6-dihydroxy indole, may be generated from the breakdown of either of the common amino acids, tyrosine or tryptophane.

*Tyrian Purple.*—A purple of the ancients, Tyrian is 6,6'-dibromindigo. It is generated in the presence of light, probably through the influence of an enzyme, from a colourless precursor secreted by

the so-called adrectal or hypobranchial gland in several species of snails of the genera *Murex* and *Purpura*. This red-violet dye has long been employed commercially in certain countries. Its physiological use to the animals producing it is obscure; in all probability it is an excretory product.

**9. Purines and Pterins.**—The purine compounds are hardly to be classed as true pigments, since they are usually white crystals. They often contribute, however, to the colour scheme of lower vertebrates and invertebrates. The position of purines as excretory products is amply illustrated by the large amounts of solid white uric acid and guanine in the excrement of birds and of uric acid in that of reptiles. Uric acid has also been found in the yellow sheets of mucus excreted by sea anemones, and urates are present in small amounts in the urine of man and of the higher apes. (Pathological deposition of sodium urate in the joints is a factor responsible for gout [*q.v.*].)

The brilliant whiteness of some anemones, notably the white variant of *Metridium senile*, results partly from microcrystalline deposits of uric acid in the tissues. These crystalline aggregates are especially noticeable in the mesenteries. Other purines, such as xanthine, have been reported as occurring in the wings of pierid butterflies. Mention has already been made of the notable deposition of guanine crystals in the leucophores or iridocytes of fishes, contributing a whiteness or often a brilliant silvery appearance to extensive areas of the skin. Purine compounds constitute part of the complex nucleic acids which abound in the nuclear material of all cells; it is therefore presumed that they play an indispensable part in cell metabolism. The purine compound hypoxanthine exercises a specific stimulating and accelerating effect upon the growth of embryonic tissues of the chick.

Some fishes vary the quantities of deposited guanine (fig. 12) in proportion to the lightness of the background upon which they are living. In a study of the effects of the albedo (ratio of reflected to incident light) upon the black and white pigmentation of fishes' skins, it was demonstrated that the greenfish or opaleye (*Girella nigricans*) kept in white-walled containers became very pale during a four-month period. These fishes stored about fourfold the quantity of integumentary guanine as did the skins of fish kept in

black-walled aquariums. The skins of the fish in the latter group, intensely black in colour, yielded more than twice the total quantity of melanin. This was a unique demonstration of two alternative, very different biochemical reactions, catalyzed in opposite ways by the total light entering the eyes of the fishes, *i.e.*, high albedo stimulating the deposition of guanine while depressing the formation of the end product, melanin; and low albedo exerting the opposite effects. (See fig. 10.)

Closely related to the purines, and formerly classed among them, are the so-called pterins, which derive their name from their notable appearance in, and primary chemical isolation from, the wings of certain butterflies. Pterins are encountered as white, yellow, orange, or red granules in association with the wing material. They contribute the yellow colour to the bodies of many wasps. Pterins are soluble in aqueous solutions, often more

FIG. 13.—XANTHOPTERIN

so in the presence of ammonia, and insoluble in the usual organic solvents. Leucopterin is a white compound obtained from the white butterflies *Pieris brassicae* and *P. napi*, and has been found accompanied by xanthopterin in other species. Xanthopterin (fig. 13) is a yellow pigment responsible for the yellow colour in the wings of *Gonepteryx rhamni* and other butterflies, and in the abdominal skin of wasps (*Vespa* species). It occurs also in human urine, and therefore has been called uropterin. This compound has been effective in preventing nutritional anemia in rats and in young salmon.

In butterflies, the colourless compounds guanopterin and mesopterin may be accompanied by chrysopterin, an orange compound or by a red homologue, erythropterin; the latter in particular conspicuous red colours to the wings of several species. A pigment in the eyes of the fruit fly *Drosophila melanogaster*, of great interest and usefulness to geneticists, is believed to be related to the pterin class. Fluoresceyanin, a blue-fluorescing pterin in the scales of many fishes, biochemically resembles some of the B vitamins.

Certain pterins and their derivatives are believed to deter the growth of some tumours (in experimental mice), while others have reportedly been effective in reducing pain, whether reduced experimentally or incidental to neoplastic diseases.

**10. Lyochromes (Flavins).**—This class of yellow, greenly

fluorescent, water-soluble pigments is widely distributed in plant and animal tissues, although their presence in but very small

FIG. 14.—RIBOFLAVIN

amounts usually renders their colour inappreciable in animals. Lyochromes are synthesized by bacteria, yeasts, and green plants; the lyochrome riboflavin (identical with vitamin B<sub>2</sub>) is not manufactured by animals, which thus depend upon plant material for their ultimate supply of this important factor. Riboflavin (fig. 14) is part of an enzyme capable of combining with molecular oxygen, whereupon the yellow colour develops. It may then release oxygen for intracellular oxidation processes, with simultaneous loss of colour. The colour is restored by fresh supplies of oxygen.

Blood, milk, eggs, liver, kidney, and muscle contain appreciable quantities of riboflavin. A nutritional lack of riboflavin leads to impairment of cellular respiration, retardation of growth of young mammals, and cataract development in mice, chickens, and monkeys. The compound is not stored in quantity and is a normal excretory product. It has been encountered in somewhat concentrated amounts in the Malpighian tubules of insects, which obtain it from fresh vegetable material. The larvae of mosquitoes responsible for carrying yellow fever fail to develop normally, or to complete their metamorphosis if deprived of flavin and purine.

**11. Miscellaneous Pigments.**—There are many animal colouring matters whose constitutions remain unknown. Of these, only a few of the more conspicuous examples will be mentioned.

**Chromolipoids.**—These are yellowish, reddish, or brown fat-soluble pigments often encountered in the fat droplets of eggs and other cells and in other lipid-rich tissues. They have often been mistaken for both melanins and carotenoids. Chromolipoids are believed to be derived from partially oxidized fatty acids, phospholipids, or other lipid compounds, perhaps in ways similar to those in which commercial fats may gradually become discoloured on being heated or after long standing in air.

**Hemocyanin.**—This compound is the respiratory catalyst encountered in the plasma of molluscan and crustacean blood. It is colourless in the reduced condition, but assumes a blue colour upon exposure to oxygen, with which it combines. During the circulation of the blood, the oxygen carried in combination with hemocyanin is released to the tissues requiring it. Chemically, hemocyanin is composed of a large protein complex bound to copper, whose presence is responsible for the blue colour of the oxidized molecule.

Wide differences in molecular weight have been found in hemocyanins from the blood of various species; in certain crustaceans, the value has been given as 360,000 and represents lower limits. *Limulus*, the horseshoe crab, carries a hemocyanin having a molecular weight of about 1,300,000; *Octopus* 2,000,000; and the land snail *Helix* as high as 5,000,000.

The blue oxyhemocyanins of various mollusks and arthropods commonly exhibit a broad spectroscopic band of light absorption in the yellow to orange region. The fact that hemocyanins possess only about one-fourth the oxygen-combining capacity of the commoner hemoglobins explains in part why species endowed with hemocyanin are subject to relatively depressed metabolic activities, e.g., as in certain bottom-dwelling snails, or are extremely sensitive to asphyxia as are squids.

**Hemerythrin.**—Hemerythrin is an iron-containing proteinaceous pigment present in the blood of certain bottom-dwelling marine worms and of the brachiopod *Lingula*, serving as a reversible oxygen carrier as do hemoglobin, chlorocruorin, and hemocyanin.

The blood containing hemerythrin is pale in the reduced condition, becoming red or reddish-brown when oxygenated.

**Vanadium Chromogen.**—This compound is the pale-green pigment within the blood cells (so-called vanadocytes) of sea squirts belonging to the families Asciidiidae and Perophoridae. The vanadocytes are rounded, mulberry-shaped cells, varying but little in shape or size among different species. The diameter is about that of the disc-shaped red blood cells or erythrocytes of mammals, about eight microns. Within each vanadocyte are about eight to ten relatively large, apple-green bodies containing the pigment.

**Actinochrome.**—This red or violet pigment in the tentacle tips and mouth opening of various sea anemones is not to be confused with either the carotenoid or the heme classes of pigment. Insoluble in ether, chloroform, and in most other common fat solvents (except acetone), it may be extracted from the fresh tissues with glycerol, to which it imparts its red colour, with the display of several characteristic absorption bands; one of these has its maximum in the yellow region, another is located in the blue range. The physiological significance of actinochrome is unknown.

**Adenochrome.**—This red pigment, occurring in high concentrations in the branchial heart tissues of *Octopus bimaculatus*, is readily soluble in dilute ammonia or other alkalis, conferring thereto a wine-red colour. Even dilute acidification causes complete precipitation of the coloured material as purple flocs. Adenochrome, insoluble in alcohol, ether, chloroform, dioxane, and glacial acetic acid, dissolves slightly in trichloroacetic acid or in dilute pyridine. Readily precipitable from aqueous alkaline solutions by the addition of alcohol and subsequently dried, the resulting mauve or purple powder fails to melt at 300° C, but chars at higher temperatures.

**Aphin.**—The hemolymph of numerous coloured species of aphids yields a series of yellow, orange, and red compounds, referred to by A. R. Todd and his associates as aphins. Fresh insects treated with hot water yield protoaphin, a water-soluble pigment crystallizable as pale-yellow needles. This protoaphin is convertible, through the action of oxidizing enzymes in freshly crushed insects, into a secondary yellow derivative, xanthoaphin, which on further oxidative changes is altered to yield chrysoaphin; and this, in turn, is similarly convertible to erythroaphin. Each of these aphins exhibits a characteristic crystalline habit, colour, and fluorescence corresponding with successive phases of oxidation.

The aphin molecule is without combined nitrogen, halogens, sulfur, or methoxy groups. Erythroaphin seems to possess phenolic hydroxyl groups; its ready chemical reduction and its reoxidation by atmospheric oxygen suggest the likelihood of a quinonoid structure.

Although protoaphin, the primary pale-yellow water-soluble aphin, is easily and extensively oxidizable through an enzyme in the hemolymph, this compound's potential physiological significance in the insect's system remains yet to be clarified.

**Other Pigments.**—Numerous coelenterates exhibit brilliant pigmentation, the chemical nature of which is as yet imperfectly known. For example, the lasting red pigment in skeletons of red coral (*Corallium rubrum*) and organ-pipe coral (*Tubipora musica*) and the red, orange, and yellow colouring matters of many other alcyonarian coral skeletons are chemically obscure.

The large, colourful, poisonous jellyfish *Pelagia noctiluca panopyra* exhibits several pigments. Blue (noncarotenoid) intracellular chromoproteins are present in the heavy, pendulous lips, the exumbrella, gonads, and gastric filaments; brown pigments occur in the outer skin of the umbrella; and a magenta-coloured chromoprotein is recoverable from the noncellular mesogloal jelly. Studies on the magenta suggest a melanoid character. (D. L. F.)

## C. FUNCTION

Under this heading are two distinct classes of functions: (a) the value to the organisms of the substances giving rise to these colours; (b) the value of the colours as such to the organisms possessing them. The first has to do with the utilization of substances that happen to be coloured; the second with value of appearance to the animal, regardless of how this is brought about.

The first of these two functions was considered in the previous

two sections in connection with the chemistry and physiology of animal pigments. As stated there, some of these coloured substances are physiologically very important to the organisms; for example, in relation to their respiratory function or as products of fundamental metabolic processes.

**1. Vision and Heat Regulation.**—Most of the pigments clearly have roles related to their specific light-absorbing or -reflecting properties. The ability of the vertebrate eye to respond to light depends upon the presence of two photoreceptive pigments, visual purple (rhodopsin) and visual violet (iodopsin), in the retinal rod and cone cells, respectively. In addition, dark pigments commonly form screens that regulate the amount of light entering the eye and restrict the directions from which light may penetrate the eye. Reflecting pigments that comprise the tapetum, giving the "eye-shine" so conspicuous in many nocturnal animals, serve to increase the sensitivity of the eye to weak, nighttime illumination.

Light-absorbing and -reflecting pigments in the skin may be involved in a primitive mechanism for temperature regulation in some cold-blooded species. In cool morning air the skin of the desert-dwelling horned toad is dark and absorbs sun's heat rays; as the temperature rises during the day, the body blanches and reflecting pigments assist in protecting the animal from further heating. A comparable adaptive colour change in relation to body temperature occurs in fiddler crabs. Some locusts regulate their rate of solar-heat absorption by changing their orientation to the sun's rays from broadside when the air is cool to parallel at higher temperatures. White in the animal kingdom is sometimes due to special white substances deposited in the tissues; in other cases it is due to the lack of coloured substances, their place being taken by air. Substitutions of this kind occur in the hair of white mammals and the plumage of white birds. The suggestion often has been made that the white plumage or pelage of Arctic animals is of value in retarding the radiation of heat.

Intense solar radiation, especially in the ultraviolet, is injurious to living matter, therefore a very general role of integumentary pigmentation is protection of the cells of the organism by light absorption or reflection. The production of the black pigment, melanin, in human skin in response to sunlight is, therefore, clearly adaptive. Here should be mentioned, too, the dense layer of pigment cells (chromatophores) that lines the peritoneum of many fishes and some other vertebrates. The function of such a layer is not known, though it may well provide added protection from sunlight for the viscera. Consistent with this protective role of integumentary pigments is a primitive response by the young of numerous colour-changing species; these tend to blanch in darkness and darken in bright light. Colourless or transparent animals are generally found in darkness or in aquatic situations where the ambient water serves as a protective filter.

Cephalopod mollusks, when disturbed, may discharge a dense cloud of black "ink" (melanin) into the water. This is commonly interpreted as a "smoke screen," serving to baffle pursuers.

**2. Concealment.**—The principles of camouflage, which became familiar after World War I, probably have been operating in the animal kingdom from the time that sight originated, with predators relying upon it to capture prey by surprise and prey depending upon it to escape observation by predators.

Naturalists have continually been impressed by the widespread existence of protective coloration, since any collector of living specimens, vertebrate or invertebrate, is constantly balked in his search for organisms that, as he may know, lie before his eyes. The prevailing sandy hues of desert animals, bluish tints of inhabitants of ocean surface waters, the whites of Arctic creatures, and the greens of animals inhabiting vegetation are familiar to the field naturalist. Less familiar are special cases where extensive areas of black volcanic rock in the desert have influenced appropriate darkening effects in animals that in surrounding areas display the prevailing pale hue. Such examples serve to refute any general explanation of the pallor of desert animals as being the result of either the direct effects of solar radiation or the animal's need for reflecting this from its surface.

There even may be orderly changes in colour during the animal's

life cycle, nicely correlated with changes in habits. The common eel is transparent, while a pelagic larva, later becoming darkly pigmented as an adult bottom-dweller in shallow water. One species of mollusk is first red as it feeds upon red algae in deep waters, later becoming olive green as it migrates to brown and green algae in shallower locations. The transient spotted or mottled patterns of many helpless young birds or mammals serve to protect them at this vulnerable stage. Annual rhythms of change in coloration occur in many animal inhabitants of the colder latitudes. The dark summer dress of such forms as the hare, ermine, Arctic fox, ptarmigan, and willow grouse gives way to white at the onset of winter.

The importance of the principle of protective coloration as a factor in evolution was fully recognized by Darwin and some of his contemporaries, and it soon became one of the standard examples of the working of natural selection. It required considerable sophistication for zoologists of a later generation to question the testimony of their senses and to demand that a protective value of coloration be more critically established. However, more extensive knowledge, including experimental evidence showing that protective coloration does in reality protect, led to a return toward the views of Darwin and his followers.

If, in these cases, merely a general resemblance in colour between the organism and its usual environment had to be considered, some direct physical or chemical influence of the latter upon the former might be sought, as has been done by some critics of natural selection. But frequently the coloration and form of animals assume such highly specialized character as to constitute veritable disguises. Instances of remarkable resemblance to a leaf are known in such diverse groups as insects, fishes, toads, and lizards. This disguise is enhanced by habits of posture or movement. Resemblance to the bark of trees, to small twigs, or to lichens is frequent. The most striking cases of this specialized resemblance are to be found in the special fauna of the floating seaweed *Sargassum* of certain areas of the tropical Atlantic. Here are animals, many of them belonging to widely separated classification subdivisions, not only displaying the colours of the seaweed itself but even copying the white patches of the encrusting bryozoan by which this seaweed is conspicuously mottled. In certain of these animals, too, the skin is extended into long, fleshy appendages that closely resemble similar structures upon the fronds of the weed. Anyone seeing these organisms together under natural conditions would be unlikely to consider the resemblance fortuitous. Furthermore, any naturalist with much field experience knows that correspondences of this sort are far from being rare or exceptional; specific resemblances to particular natural objects occur with such convincing frequency as to be difficult to interpret in any other terms. We must add that these resemblances in colour and structure are usually correlated with instincts that control the attitude assumed by the animal, e.g., quiescence or movements of a special sort that serve further to deceive the enemy. The walking stick, for example, would not be duly protected by its form unless it also behaved as a stick and reduced its movements to a minimum.

**Deflection and Allure.**—Two other kinds of functional coloration should be mentioned.

One of these, termed deflective marks, is illustrated by the very conspicuous "eyespot" on the wings of certain butterflies, believed by some to divert the attack by predatory birds to less vulnerable portions of the insect body; such markings also occur on the posterior parts of the body of fishes, and their effect apparently is to deceive predators as to the orientation of their prey.

A second type is that of alluring coloration. This is seen, for example, in coloured worm- and grublike processes that protrude near the mouth of certain fishes and reptiles and serve to entice prey into position for easy capture. Another example is the fluke that, upon completing one stage in its life cycle in a snail, invades the snail's tentacles and becomes brightly coloured, thus inviting ingestion by its next host, a sparrow.

**Countershading and Disruption.**—Another class of camouflage principles was recognized later than those that have to do with

Concealing coloration: the roe fawn's coat, mottled like its surroundings, provides protection from predators

Sexual dimorphism: (left) female and (right) male scarlet tanager, which show the sexual difference in colour common among birds

Alluring coloration: potential predators of the blue-tailed skink are attracted to its tail, which can be shed at will, offering the skink a means of escape

Adaptive colour change: three photographs showing the gradual colour change of an American chameleon when moved from a green leaf to a brown branch

Warning coloration: when threatened, a puss moth caterpillar raises its brightly coloured head and its tail horns to intimidate its attacker; normally, the caterpillar is inconspicuous

Specialized resemblance: sargassum sea slugs, one of many animals that look remarkably like the seaweed, *Sargassum*, in which they live

Seasonal colour change: the varying hare changes colour to blend into its environment. (Top) Winter pelage; (bottom) summer pelage

Adaptive colour change: the common octopus changes its colour dramatically and rapidly under stress. (Top) The octopus, at rest, blends with its surroundings; (bottom) when agitated, it blanches

Specialized resemblances: the coloration of many insects, combined with their habits of posture, provides a natural disguise that makes them virtually invisible to predators. (Left) A hawkmoth may pass unnoticed on the bark of a tree; (right) a Malayan orthopteran can barely be seen among the leaves in which it lives

Adaptive colour change: In the heat of day, the skin of the regal horned toad (a desert lizard) blanches, and reflecting pigments help to keep it cool. At other times, the skin is dark and absorbs sun's rays

Disruptive coloration: the bizarre black-and-white pattern on the butterfly fish breaks up the body outline and renders the fish unrecognizable to enemies

Deflecting coloration: the conspicuous "eyespot" on the wings of the io moth are thought to divert the attention of attacking birds to less vital parts of the body

general conformity to background or resemblance to specific objects. This concerns colours or patterns that make the organism inconspicuous or unrecognizable, regardless of background. For the acceptance of these principles, chief credit must be given to Abbott H. Thayer, a U.S. artist, whose discoveries in this field were first announced in 1896 but were not given wide publicity until 1909. The first of these principles is that of countershading or obliterative shading, which had, however, been clearly stated by E. B. Poulton a few years earlier. This principle is a generalization of the fact that in the great majority of animals, both terrestrial and aquatic, the dorsal surface of the body is more heavily pigmented than the ventral, while there is a gradient of pigmentation from one to the other. Thayer called attention to the fact, which he illustrated by solid models, that such a distribution of pigment makes for minimum visibility, when the animal is lighted, as it most commonly is, from overhead.

Another principle stressed by Thayer, and one that has been widely adopted, is that of disruptive patterns. In such cases the natural continuity of the body's outline is broken by intrusions of black or white or other colour at the margins, or a less conspicuous general colour scheme of the body is nullified to the observer by conspicuous markings that are quite irrelevant to this. The effect is to render an object unrecognizable even though it remains in full view. Under the name coincident disruptive colouring, H. B. Cott discussed a group of cases in which disruptive patterns were carried continuously through regions of the body that are not morphologically continuous, e.g., pigmented bars that run crosswise upon the hind legs of a frog but are evident only when the animal's legs are doubly folded in the resting position. Such colouring effectively obscures the presence of the appendages. Similar pigmented stripes, arranged longitudinally, frequently include the eye, camouflaging what is otherwise a most conspicuous organ. The stripes at the same time divide the body into two or more longitudinal sections and tend to render it unrecognizable as a single organism of familiar form.

Since shadows cast by animals may constitute an effective means of exposure, shadow camouflage has been commonly accomplished by crouching posture, by compressed form of the body, or even by the use of special disruptive patterns to produce false shadows.

**Adaptive Colour Change.**—Many animals, representing several different major subdivisions of the animal kingdom, are able to cause their shades or in some cases their actual colours to conform to those of their background. These changes are mediated through the eyes and the central nervous system, in some cases involving endocrine glands. The effector organs are the chromatophores, the highly branched special cells in the skin or elsewhere. The most familiar of these are black, white, yellow, and red in colour. Colour changes of this type have been most fully investigated in fishes, Amphibia, and reptiles among the vertebrates and in crustaceans and the cephalopod mollusks among the invertebrates. The literature in this field has become very extensive.

Colour changes resulting from chromatophore action are of two kinds. The first are rapid changes, often completed within a few minutes or even seconds. They are brought about by the aggregation or dispersion of pigment granules within the chromatophores. The aggregated condition results in a withdrawal of much of the pigment from view and thus to a paling of the animal. On the other hand, the dispersion of pigment leads to a darkening of the chromatophores and thus of the surface of the body as a whole.

The second type of colour change usually involves an increase or decrease in the number of chromatophores present, as well as in the actual amount of pigment contained in each. Such changes result from prolonged subjection of the animal to the same stimuli that call forth the more familiar, immediate results. In either case, it is important to note that the shade assumed or the amount of pigment produced is dependent not upon the absolute degree of illumination to which the animal is subjected but upon the albedo of the background; i.e., the ratio of reflected to incident light. The amount of melanin present at the end of four months in one species of fish was found to be about twice as great in specimens kept on black as in those kept on white backgrounds, while

the amount of the white pigment guanine was four times as great in the latter as in the former. The differences in appearance of the fish were very striking. The black-adapted specimens were almost completely black, the white-adapted ones were pale gray.

Evidence that this capacity for pigmentary adjustment to background may be of lifesaving value to fishes has been obtained experimentally. Large numbers of fishes that differed widely in the extent to which this adjustment had been carried were subjected to attacks by fish-eating birds and larger fishes. It was found that the ratio between less-adapted to more-adapted fishes among the casualties was consistently high, averaging about two to one.

Aside from such tests, however, the mere existence of the mechanism for adjustable coloration would seem to constitute strong evidence for the effectiveness of protective coloration; this complicated mechanism has evolved independently in several unrelated branches of the animal kingdom. Furthermore, so far as aquatic animals are concerned, no plausible function except concealment has ever been suggested. Two other facts strengthen the argument even more. The adjustment of some fishes and crustaceans to their backgrounds includes pronounced and appropriate changes in colour pattern that can have no significance except as they affect appearance; the old familiar objection to the protective coloration theory that many of the presumed predators are not known to possess colour vision loses its force completely in the face of these facts. Further, it has been observed that crustaceans, fishes, and lizards, given a choice, will tend to select a background in harmony with their skin colour.

**3. Warning.**—Many animals, especially insects, that are edible and inoffensive have developed a superficial resemblance to other species, often widely unrelated to themselves, that are avoided by predators owing to the possession of repellent or dangerous characteristics (see *MIMICRY*) such as venomous stings or bites, objectionable flavour, or poisonous flesh. This earliest discovered (Batesian) type of mimicry is supplemented by another (Müllerian) type in which a number of species of animals that are similarly obnoxious appear to have adopted a common conspicuous (aposematic) livery, supposed to be recognized by predators as belonging to animals that should be left alone.

Warning or aposematic coloration is usually achieved through display of bold patterns of combinations of such striking colours as red, yellow, orange, black, and white. These stand out conspicuously against the usual green or brownish backgrounds. Such species also tend to have habits that render the colours more conspicuous. Although usually sluggish and indifferent, they tend to move when threatened and are commonly gregarious. They are typically diurnal in their activity, hiding at night. They also hide during cold or dry periods when, because of a scarcity of other foods, there would be less immunity from potential predators. Avoidance of aposematic species appears in many instances to be a response learned by each individual predator; any learning carry-over would be distinctly advantageous to both the attacker and the attacked. Experiments by a number of naturalists provide evidence indicating that birds, monkeys, and perhaps some other animals exercise choice in the selection of insects and tend to reject those that have certain brightly coloured patterns.

**4. Recognition.**—This term has been applied to certain cases in which conspicuous markings are displayed. The markings may serve to identify an animal in the eyes of another of the same species, either at the time of mating or when they are flocking together for mutual protection. The white flag of the retreating cottontail rabbit and the showy rumps of some of the deer frequently are cited as examples of aids to identification for mutual protection.

In many species of animals the sexes differ widely in colour. The most familiar examples of this are found among the birds, fishes, and insects. In cases where one sex is more highly coloured or more ornate than the other, it is usually the male that is so characterized. In some birds and fishes these sexual differences of colour become greatly emphasized during the breeding season, diminishing or disappearing during the periods of sexual inactivity.

Among birds, colour changes are usually a consequence of feather replacement following the spring molt or less frequently are caused

by the shedding of the tips of feathers. The plumage coloration differences between the sexes of birds are variously determined by hormones and genes. In domestic fowl, hormones from ovary or testes are the agents, and in the English sparrow the agents are the genes alone. In male weaver finches, pituitary hormones (gonadotrophins) determine the bright coloration, while ovarian hormones inhibit coloration in the female. Similar diversity of control is known for the sex differences in bill colour among birds. Sex hormones appear involved with the colour differences in fishes. In insects, however, the differences depend exclusively on genic control.

A question quite different from that of the physiological basis of sexual colour differences is that of the utility of these colours, if any, to the organism. Are the gorgeous colours of male birds, for example, of advantage to the wearers of these colours? Darwin, as is well known, answered this question in the affirmative with his hypothesis of sexual selection. The showy characters of the male plumage, he contended, arose through the continued selection by the females of the more ornate mates. Darwin was able to point to cases among birds in which competitive display by the males and selection by the females seemed to be incontrovertible facts. The extraordinary perfection to which certain colour schemes have been carried (e.g., in the secondary wing feathers of the male argus pheasant) speaks for a level of aesthetic appreciation that certainly would not have been expected in a bird. However, the range of colour differences that can reasonably be explained by this sexual selection theory is certainly much less extensive than Darwin supposed, and in those cases for which it is regarded as relevant the theory has undergone considerable changes in its formulation (see also SELECTION). One alternative explanation offered by A. R. Wallace to account for certain sexual differences of coloration in birds would seem to have considerable merit. Wallace contended that some of these differences might be due to an adaptive modification of the brooding female for purposes of concealment. Species with brightly coloured females usually have concealed nests, and in species in which the male is known to brood the eggs this sex possesses a cryptic coloration. Indeed, the suggestion has been made that it might be advantageous to the species for the male to be more conspicuous during the nesting season in order to divert the attention of predators from the female, who at that time is biologically more important.

It must be admitted that for many of the general differences in coloration among animals no explanation has been found, and, perhaps no explanation of a specific adaptive nature is called for. Many may eventually be found incidental to the animal's metabolism and simply to have persisted to an extent and in a form permitted by natural selection. See ADAPTATION, BIOLOGICAL; EVOLUTION, ORGANIC: *The Species Concept*; FISH: *Description: General Features: Colour*; HORMONES: *Invertebrate: Hormones and Colour Change*; MELANISM. (F. A. BN.)

## II. PLANT COLOURS

The colours of the plant world are predominantly the green of leaves and stems, attributed to chlorophyll; the yellow and orange of many flowers, fruits, and leaves, attributed to carotenoid pigments; and the red, blue, and pale yellow of flowers and fruits, attributed to flavonoid pigments. The flavonoids include the anthocyanins, responsible for red, blue, mauve, purple, and violet colours, and the anthoxanthins (comprising the flavones, flavonols, flavonones, etc.), ranging from colourless to yellow. The anthoxanthin pigments, while universally distributed in plants, generally contribute little to the visible colours of petals and leaves in which they occur. White flowers—which are often actually pale ivory or cream-coloured—usually contain anthoxanthin pigments, the presence of which can be recognized by the yellowing that occurs upon exposure of the petals to the vapours of ammonia.

Most flower petals, white or coloured, contain mixtures of two or more kinds of pigments. Brownish and red-orange flower petals owe their colour to the presence of mixtures of anthocyanins and carotenoids. Yellow flowers usually contain carotenoids and flavones, but certain yellow flowers, such as the garden coreopsis

or tickseed, are pigmented by mixtures of carotenoids and the deep yellow-orange benzalcoumaranone (aurone) pigments. It is to a member of the latter class of substances that the yellow colour in the lips of the ivory-coloured garden snapdragon is due.

The autumnal reddening of leaves is due to the disappearance of chlorophyll and the formation of anthocyanins. Anthocyanin formation is promoted by high light intensity and low temperatures. Thus, autumnal colouring is often most striking when a succession of clear, sunny days precedes the advent of frost.

Certain mineral deficiencies in plants often contribute to and can be recognized by the formation of red anthocyanin coloration. Phosphorus deficiency in tomatoes, calcium deficiency in corn (maize), and boron, zinc, or molybdenum deficiencies in other plants often manifest themselves by the appearance of reddening of the leaves and stems. However, such reddening can occur only in those plants that possess the genetic factors necessary for the synthesis of anthocyanins.

Disease and injury often cause reddening of the affected plant as a result of derangement of normal metabolic processes and consequent diversion of synthetic pathways toward anthocyanin formation. On the other hand, virus infection is also known to cause the disappearance of normal anthocyanin pigmentation. The "breaking" of red flowers to white in virus-infected stock (*Matthiola incana*) and sweet pea (*Lathyrus odoratus*) is a well-known example.

Pigments of plants may be classified according to the way they occur in the plant, whether in discrete bodies called plastids or simply dissolved in cell sap. Plastid pigments are soluble in fat solvents like ether; they include the chlorophylls and carotenoids. Vacuolar pigments in the cell sap are water soluble; they include the flavonoid compounds. (T. A. G.; X.)

### A. PLASTID PIGMENTS

**1. Chlorophyll.**—Chlorophyll, one of the most important pigments in nature, is capable of channeling the radiant energy of sunlight into chemical energy usable in the reactions of the cell through the process called photosynthesis. A pigment very much like chlorophyll, a light-trapping substance, was probably the first step in the evolution of self-sustaining life. Chemically, chlorophyll is related to the respiratory enzymes called cytochromes and to the heme portion of the red blood pigment hemoglobin. Chlorophyll exists in several forms. Chlorophylls *a* and *b* are the chief forms in higher plants and green algae while combinations of *a* with *c* or *d* occur in different algae; bacteriochlorophyll is found in certain photosynthetic bacteria. Chlorophyll *e* is a rare pigment first demonstrated in one of the golden algae. Protochlorophyll, a presumed precursor of chlorophyll, is found in etiolated seedlings and plants grown in inadequate light. Chlo-

FIG. 15.—CHLOROPHYLL *a*

robium chlorophyll (bacterioviridin) is found in green bacteria.

The chlorophylls are magnesium porphyrin compounds in which four pyrrole rings are attached to a single central magnesium atom. The different forms differ in minor modifications of side groups attached to the pyrrole rings. Basically, the chlorophyll molecule consists of two portions: a flattened square, the tetrapyrrole configuration, and a long tail formed of phytol, found also in vitamins K and E. In higher plants chlorophyll is bound to proteins and lipids as chloroplastin in definite and specific laminations in bodies called chloroplasts.

The pure chlorophylls are usually obtained as dark-green waxes. Progress in purification has enabled both chlorophylls to be characterized more precisely by their absorption spectra and, finally, to be crystallized, component *a* being obtained in green hexagonal plates and component *b* in dark-green needles. The methods employed for the identification of the chlorophylls and for their quantitative determination are based upon characteristic absorption and fluorescence spectra. For their work on the structure of the chlorophylls R. Willstätter received the Nobel Prize for Chemistry in 1915 and H. Fischer received it in 1930.

The chlorophylls contain two hydrogen atoms more than the porphyrins, which possess the maximum possible number of double bonds in the ring system. Magnesium, bound in the form of a metallic complex, forms an essential component of the molecules of the natural chlorophylls. It may be that the magnesium has a share in the part played by chlorophyll in the assimilation process. The magnesium atom also constitutes a characteristic difference between the chlorophylls and the blood pigment hemin, which is an iron complex but otherwise possesses a similar structure, including a porphyrin system whose substituents agree closely with those of the chlorophyll porphyrins. When the chlorophylls are treated with acids, the magnesium atom is easily split off, the colour then changing from pure to brownish green. The magnesium can be replaced by copper, zinc, or other metals. The corresponding copper complexes are stable and are used as industrial pigments; e.g., in the soap and cosmetic industries.

The phytol radical is derived from the simple unsaturated alcohol phytol,  $C_{20}H_{39}OH$ . Phytol, as a structural component of vitamins E and K, is connected with special physiological functions.

Chlorophyll *b* differs from chlorophyll *a* only in having an aldehyde group in position 3 in ring II in place of a methyl group; i.e., it has an oxygen atom in place of two hydrogen atoms. The complete chemical synthesis of chlorophyll was accomplished by R. B. Woodward and co-workers in 1960.

As precursors of the chlorophylls in plants, protochlorophylls were found which are converted into chlorophylls on exposure to light. It is probable that these protochlorophylls belong to the porphyrins but otherwise possess the same structure as the chlorophylls.

Bacteriochlorophyll can be derived from chlorophyll *a* by the addition of two H atoms to the double bond in ring II and by replacing the vinyl group in position 2 by an acetyl group. Compared with the spectra of the other chlorophylls, the absorption bands of bacteriochlorophylls are shifted into the infrared.

The function of chlorophyll in photosynthesis (*q.v.*) has been defined as that of an energy transformer or of an assimilatory ferment. The path of the assimilated carbon, from carbon dioxide to the final products, especially in the case of sucrose, has been traced using radioactive carbon. The intermediates were identified by means of radioautographs and chemical analysis.

The combination of chlorophyll with protein in chloroplastin is of special significance for this function, since only as a result of this combination is chlorophyll able to remain resistant to light. Chloroplastins from different plants are not identical. A characteristic of chloroplastin is its great tendency toward agglomeration; and even the smallest molecular weights run into several millions.

See PHOTOSYNTHESIS; PLANTS AND PLANT SCIENCE: *Plant Physiology*; *Photosynthesis*.

**2. Carotenoids.**—The yellow to orange-red carotenoids are the most ubiquitous colorants in nature. Their universality seems to

bespeak some basic, but as yet unknown, significance for all living things. Their occurrence in animals has already been discussed under *Animal Colours: Pigments (Biochromes)*, above. Carotenoids in plants are frequently masked by other pigments, especially chlorophyll, with which they are closely associated in the chloroplasts. Carotenoids that show up clearly in certain flowers, fruits, and roots occur in plastid bodies called chromoplasts.

Carotenoids are fat-soluble pigments of two major types: the hydrocarbon class, or carotenes; and the oxygenated class, or xanthophylls. Carotenes are found in mature green leaves, carrots, sweet potatoes, tomatoes, reddish flesh of watermelons, and citrus fruits; xanthophylls occur in green leaves, yellow seeds (e.g., corn or maize), tomatoes, flowers (yellow pansies and marigolds), citrus fruits, brown algae, and diatoms. The basic carotenoid molecule, with 40 carbon atoms in a chain, can exist in more than 70 variants because of the varying number and points of attachment of hydrogen and other groups. Curiously, the phytol tail of the chlorophyll molecule resembles a short carotenoid chain with minor differences. This similarity, and experimental evidence, indicates that carotenoids are the precursors of the phytol part of the chlorophyll molecule.

The function of carotenoids in plants is thought to be closely tied in with photosynthesis, as a partner with chlorophyll. It is also involved in, among other things, the phototropic bending of seedlings and phototactic movements of bacteria and certain algae.

#### B. VACUOLAR PIGMENTS

The flavonoids or bioflavonoids comprise widely distributed water-soluble plant pigments that occur throughout the sap in the vacuoles of cells. They are chemically based on the 15-carbon atom skeleton of a compound called flavone ( $C_{15}H_{10}O_2$ ) by replacement of one or more hydrogen atoms with hydroxyl groups ( $-OH$ ) or sometimes with methoxyl groups ( $-OCH_3$ ). They occur in living tissue mainly in combination with sugar molecules as glycosides. The different classes of flavonoids can be considered, for convenience, as belonging to two major groups: anthocyanins and anthoxanthins. Anthocyanins in the extracted form, without sugar, are called anthocyanidins.

##### Anthocyanidins:

Pelargonidin—orange-red  
Cyanidin—crimson  
Delphinidin—blue

##### Anthoxanthins:

Flavones:  
Apigenin—colourless  
Luteolin—yellow

##### Flavonols:

Kaempferol—pale yellow  
Quercetin—very pale yellow  
Myricetin—very pale yellow

##### Flavanones:

Naringenin—colourless  
Hesperitin—colourless

The chemical affinities between the anthocyanins, anthoxanthins (including the flavones, flavonols, etc.), chalcones, and benzal-coumaranones are discussed in *Chemical Relationships*, below.

**1. Anthocyanins.**—The anthocyanins are largely responsible for the red colouring of buds and young shoots and the purple and purple-red colours of autumn leaves. The red colour becomes apparent when the green chlorophyll decomposes with the approach of winter. Intense light and low temperatures favour the development of anthocyanin pigments. Some leaves and flowers lose anthocyanins on reaching maturity, whereas others gain in pigment content during development. Often an excess of sugars exists in leaves when anthocyanins are abundant. Injury to individual leaves may be instrumental in causing the sugar excess in such cases.

The development of characteristic colorations in parts of plants is often useful in the diagnosis of mineral deficiencies in the plant nutrient supply. This is particularly true for phosphorus, potassium, magnesium, and boron deficiencies. Insufficient phosphorus supply induces a pronounced development of purple coloration in the leaves and stalks of some strains of corn. Development of brown, bronze, red, or purple areas in leaves is often characteristic of potassium deficiencies in potato, cotton, cabbage, apple, and orange plants. Boron deficiency causes development of a red coloration in alsike clover and alfalfa leaves. Magnesium deficiency in cotton gives rise to the production of leaves that are coloured a beautiful purplish-red between the dark-green veins. These changes are due to the production of large quantities of

anthocyanin pigments, probably followed by destruction of chlorophyll. Anthocyanin formation in such deficiency diseases can take place only in plants that possess the specific genetic factors necessary for this pigment production.

One of the most interesting and obvious properties of the anthocyanins is the change of colour they exhibit when treated with acids or alkalis. The exposure of a red flower petal to (alkaline) fumes of ammonia will cause it to turn blue or green; a blue flower will turn red when touched with vinegar or a mineral acid.

The green colour results from the combined effect of yellow and blue pigments: the bright yellow colour is produced by the action of the alkali on an almost colourless anthoxanthin in solution; the blue colour is produced by the anthocyanin. Many white flowers (e.g., jasmine and *Antirrhinum*) develop bright-yellow colorations in ammonia. A typical anthocyanin is red in acid solution, violet in neutral solution, and blue in alkaline solution. Thus, the blue cornflower, the bordeaux-red cornflower, the deep-red dahlia, and the red rose contain one and the same anthocyanin, the variation in colour simply being due to the different degrees of acidity and alkalinity of the cell sap. More than one anthocyanin may be present in a flower or blossom, and the colours of many flowers are due to the presence of both anthocyanins and plastid pigments in the tissues. Yellow wallflowers contain a plastid pigment and an anthoxanthin that contribute very little to the total tinctorial effect; the different shades of red wallflowers are due to varying proportions of anthocyanin and plastid colouring matters. Moreover, very small genetic changes in varieties or species may be associated with the development of different anthocyanins.

Colour in flowers is inherited according to Mendelian inheritance laws. In some cases single genetic factors can control the presence or absence of anthocyanins and in others two or even three factors are necessary (i.e., must be present as dominant genes) for pigmentation. Genetic factors also exercise control over the chemical structure of anthocyanins and anthoxanthins.

The principal chemical factors affecting the colours in cell sap are: (1) the nature and concentration of anthocyanins; (2) the state of aggregation of the anthocyanins, which is affected by the acid-base condition (pH) and by protective colloids such as pentosans; (3) the presence of co-pigments; and (4) possibly the presence of alkaloids and metallic complexes.

In 1905 Hans Molisch demonstrated the existence of anthocyanin crystals in the living plant, and showed that crystals of these pigments could be prepared on a small scale by simple methods. Victor Gräfe, a few years later, isolated an anthocyanin pigment in quantity and in a fairly pure condition. Knowledge of the chemistry of the anthocyanins is, however, chiefly due to Richard Willstätter, who, in a series of masterly researches, opened this new chapter of organic chemistry.

In 1913 Willstätter and A. E. Everest published an account of an investigation of the pigment of the blue cornflower. They found that the colouring matter cyanin exists in the plant as its blue potassium salt, but that the substance can also react with acids to form red salts and that advantage may be taken of this property in the isolation of the pure substance as cyanin chloride.

Cyanin chloride has the formula  $C_{27}H_{31}O_{16}Cl$  and, like all anthocyanins, contains sugar in a combined form. This is readily detached by the action of boiling 20% hydrochloric acid, leaving a salt, termed cyanidin chloride, which tinctorially and in many other properties closely resembles cyanin chloride. The sugar so detached is glucose ( $C_6H_{12}O_6$ ). Each molecule of cyanin chloride gives rise to one of cyanidin chloride and two of glucose:

Cyanin chloride is thus a diglycoside of cyanidin chloride.

Mecocyanin chloride from the poppy (*Papaver rhoeas*, purple-scarlet variety) has the same composition as cyanin chloride and, like it, is degraded to cyanidin chloride and glucose (two molecules). There are differences, however, among them—a solution of cyanin in aqueous sodium carbonate is blue, whereas that of mecocyanin is violet. The explanation for these divergencies must be sought in the different mode of the molecular attachment of the cyanidin and glucose complexes in the two substances.

Chrysanthemin, the pigment of the deep-red garden chrysanthemum, resembles mecocyanin, but its molecule gives rise to only one molecule of glucose to each molecule of a cyanidin salt; it is monoglycosidic. Very careful treatment of mecocyanin with hydrochloric acid causes the loss of only one glucose molecule, and the result is chrysanthemin chloride. Other anthocyanins derived from cyanidin are known; their differences may be traced to the varying nature of the sugars, to the number of sugar molecules attached to one of cyanidin, and to the position of such attachment. In the magenta snapdragon the pigment is a cyanidin glycoside containing one molecule of glucose and one of rhamnose.

The further work of Willstätter and his colleagues brought to light the curious fact that, despite the existence in nature of a range of colour unrivaled by art, the number of fundamental sugar-free pigments of the type of cyanidin chloride, termed anthocyanidins, is very limited. There are but three fundamental anthocyanidins: cyanidin, pelargonidin, and delphinidin. These in turn have been found to be built upon the same molecular plan, the discussion of which follows (see *Chemical Relationships*, below).

The chemistry of anthocyanin pigments is important to the canning industry. Anthocyanins of fruits form insoluble salts of tin and iron after these metals are made available by corrosion of the cans initiated by fruit acids. Thus, high anthocyanin content may greatly increase the corrosion over that which could be attributed to the acid alone. Fruit quality is thereby lowered.

Of the class of natural substances called leucoanthocyanidins some give rise, upon treatment with strong acids, to anthocyanidins that do not occur naturally. For instance, melacacidin gives an isomer of cyanidin, 3,3',4',7,8-pentahydroxyflavylium (chloride). The leucoanthocyanins and leucoanthocyanidins that give pelargonidin, cyanidin, and delphinidin are known to occur in plants, but none of these leucoanthocyanins has been isolated as a pure substance.

**2. Anthoxanthins.**—The main features of the chemistry of the anthoxanthins were well established before any real insight into the nature of the anthocyanins had been obtained. The anthoxanthins, like the anthocyanins, are glycosides, diglycosides, or rhamnoglycosides and are more widely distributed in different plants and in different plant parts than are the anthocyanins. Anthoxanthins usually impart no conspicuous colour to the plant parts in which they are found. Most flowers, white or coloured, contain them as do leaves, stems, pollen, and other plant parts.

A typical anthoxanthin is the flavonol quercitrin ( $C_{21}H_{20}O_{11}$ ), which is widely distributed in nature. Its name is derived from the botanical name for the oak, *Quercus*, from a species of which it was first isolated. On boiling with hydrochloric acid, quercitrin is hydrolyzed to the products quercetin ( $C_{15}H_{10}O_7$ ) and the sugar rhamnose ( $C_6H_{12}O_5$ ). Quercetin, a bright-yellow, feebly acid substance, combines with strong acids to form orange salts not very stable and readily dissociated by water. Nevertheless, this property of salt formation, a weaker manifestation of the basic character of the anthocyanins, is due to a structural peculiarity common to both the anthoxanthins and anthocyanins. Quercetin is a strong polygenetic dyestuff; i.e., it yields more than one colour depending on the mordant used. On wool with a chromium mordant it gives a reddish-brown shade; with an aluminum mordant, a brownish-orange shade; with a tin mordant, a bright-orange shade; and with an iron mordant, an olive-black shade.

As with the anthocyanins, different glycosides yield the same fundamental colouring matter since the colour resides in the non-sugar portion of the molecule, and, moreover, the —OH (hydroxyl) groups are sometimes replaced by —OCH<sub>3</sub> (methoxyl) groups. Derivatives of quercetin have been obtained from capers, buckwheat, clover flowers, onion skins, tea leaves, bark of the apple tree, and many other sources. Although significance must be attached to this remarkably wide distribution of quercetin, it is to be noted that nature provides more variety among the anthoxanthins than among the anthocyanidins. They are already a numerous clan, and fresh representatives are constantly being discovered.

Among the better known of the anthoxanthins the following may be mentioned (in all cases, except possibly chrysin, the substances occur in the plant in combination with sugars): chrysin ( $C_{15}H_{10}O_4$ )

is contained in the leaf buds of the poplar; apigenin ( $C_{15}H_{10}O_5$ ), in the leaves, stem, and seeds of parsley and also in camomile flowers; galangin (also  $C_{15}H_{10}O_5$ ), in galanga root; luteolin ( $C_{15}H_{10}O_6$ ), in weld. Weld (*Reseda luteola*), a herbaceous plant, the extract of which yields one of the oldest-known European dyestuffs, is said to have been used by nations north of the Alps in the time of Julius Caesar. An extract of weld gives a beautiful and fast yellow on silk mordanted with alumina, and once found a limited application in the dyeing of certain materials used in military uniforms. Kaempferol (also  $C_{15}H_{10}O_6$ ) occurs in *Delphinium consolida*, and a third isomeride, fisetin, is found in the wood of *Rhus cotinus*. Myricetin ( $C_{15}H_{10}O_8$ ) is found in the box myrtle of China and in numerous other plants; its isomerides, gossypetin and quercetagenin, are the colouring matters of yellow cotton flowers and the African marigold, respectively.

Anthoxanthins as dyes have been superseded by synthetic coal tar derivatives (see DYES AND DYEING).

**3. Chemical Relationships.**—Two of the rings in the flavone molecule are benzene rings and the third, containing an oxygen atom, is a pyrone ring. The various positions in the flavone nucleus are denoted by numerals, and the positions of —OH groups in some of the anthoxanthins are as follows: chrysin, 5,7; apigenin, 4',5,7; galangin, 3,5,7; luteolin, 3',4',5,7; kaempferol, 4',3,5,7;

FIG. 16.—FLAVONE MOLECULE

fisetin, 3',4',3,7; quercetin, 3',4',3,5,7; morin, 2',4',3,5,7; myricetin, 3',4',5',3,5,7. The nine representatives cited and several others have been synthesized by methods such as to leave no doubt in regard to their molecular structure. An —OH group in position 3 has a considerable influence on the properties of the pigments; those that contain it are called flavonols and are usually characterized by more powerful tinctorial properties and greater strength as bases than isomerides not hydroxylated in this position. It has been found that the sugar molecules are usually attached through oxygen atoms in positions 3 or 7. When 3 position is saturated with hydrogen atoms the compound is called a flavanone; such pigments are found in citrus peel.

FIG. 17.—ANTHOCYANIDINS

The formulas of three anthocyanidins are shown in fig. 17. These may be compared with certain flavonols expressed similarly (fig. 18).

FIG. 18.—FLAVONOLS

It seems probable that in the living plant the anthocyanins and anthoxanthins represent end products obtained by divergent processes from a common substance. Nevertheless, it is known that genetic factors that govern the hydroxylation pattern of the anthocyanins also exert a corresponding control on the structures of the noncyanic pigments.

In favour of the hypothesis that anthocyanins are formed by the direct reduction of flavones may be counted the circumstance that, as far as is known, the groups such as —OCH<sub>3</sub> and sugar groups that are attached to the fundamental chemical nuclei often occupy corresponding positions in the anthoxanthins and anthocyanins—e.g., the formulas of peonidin chloride, the anthocyanidin from the peony, and isorhamnetin, the anthoxanthin from yellow

FIG. 19.—RELATED FLAVONOIDS

wallflowers, may be compared. Both have been synthesized.

The sugar residue is frequently attached to position 3 in both anthoxanthins and anthocyanins. The second sugar residue of the dimonoglycosides usually occupies position 5, a position that is only rarely occupied by a sugar in the anthoxanthins. It is generally recognized that the diglycosides in both series contain disaccharide units. That is, the attachment involves only one —OH group of the anthocyanidin.

**COLORIMETRY**, the measurement of wave length and of the intensity of electromagnetic radiation in the visible region of the spectrum. It is used extensively for identification and determination of concentrations of substances which absorb light. Two fundamental laws are applied, the one of Pierre Bouguer (also known as Lambert's law), which relates the amount of light absorbed and the distance it travels through an absorbing medium, and Beer's law, which relates light absorption and concentration of absorbing substance. The two laws may be combined and expressed by the equation  $\log I_0/I = kcd$ , where  $I_0$  = intensity of the incident beam of light,  $I$  = transmitted intensity,  $c$  = the concentration of absorbing substance,  $d$  = the distance through the absorbing solution, and  $k$  = a constant, dependent upon the absorbing substance, wave length of light used, and on units of  $c$  and  $d$ .

A simple application of this expression is found in comparing intensities through layers of different thicknesses of solutions of known and unknown concentrations of the same absorbing substance. If, when the same incident intensity is used, the transmitted intensities are equal, then  $c_1d_1 = c_2d_2$ . The concentration of unknown ( $c_2$ ) can be expressed by the ratio  $d_1/d_2$  times the known concentration ( $c_1$ ). In this visual method, Nessler tubes or a Duboscq-type colorimeter may be employed. If a photoelectric cell instead of the eye is used to compare intensities, the instrument is called a photoelectric colorimeter.

In colorimetry frequently the entire visible spectrum (white light) is used, and consequently the complementary colour of the one absorbed is observed as transmitted light. If monochromatic light or a narrow band of radiation is used, the instrument is called a spectrophotometer. It is not limited to the visible spectrum and is often employed to make measurements in the ultraviolet and infrared regions. The spectrophotometer has largely replaced the colorimeter.

Most of the chemical elements and a large number and wide variety of organic compounds may be determined colorimetrically or spectrophotometrically, frequently at concentrations down to one part of the constituent in several hundred million parts of solution. See also COLOUR: *Spectrophotometry*; *Colorimetry*.

(J. H. Y.)

**COLOSSIANS, EPISTLE TO THE.** This writing is included among the Epistles of Paul in the New Testament, and, claiming to be written by him (i, 1; i, 23; iv, 18) while a prisoner (iv, 3, 18), it belongs, with Philemon, Ephesians and Philippians (*qq.v.*), to those known as the "captivity Epistles." The determination of its date depends on decisions as to its authenticity and to the imprisonment in question.

**Polemic Against False Teaching.**—The main concern of Colossians is with the false teaching that had invaded the Christian congregations of this area of Asia Minor. Colossae stood on the banks of the upper Lycus (a tributary of the Maeander), about 12 mi. from Laodicea and about 13 from Hierapolis. Christian congregations had been founded in all three towns (Col. iv, 13), without a visit from Paul himself, perhaps (in the case at least of Colossae) by one Epaphras. It was Epaphras who, on this occasion, had brought news from Colossae and was now with the apostle (see Col. i, 7-9; ii, 1; iv, 12).

Other links between Paul and the Lycus valley churches were Philemon and his runaway slave Onesimus (Philem. *passim*; Col. iv, 9). The church at Laodicea is mentioned again in Rev. iii, 14 ff., and at Hierapolis Papias was bishop c. A.D. 130.

The false teaching in question appears to have been "dualistic" (in the sense that it regarded matter as evil), and to have regarded Christ as only one among a whole hierarchy of angelic powers and not as supreme (Col. i, 15-23; ii, 9, 14). The cult

of angels, the observance of some ritual calendar, food laws and ascetic practices, and perhaps also circumcision were included in the system (Col. ii, 11, 16-23). It is impossible to determine the precise nature and origin of this amalgam (it is of a type often called gnostic, though this was not its contemporary name; see Gnosticism). But the Dead Sea scrolls (*q.v.*) from Qumran have demonstrated the existence, even on Palestinian soil, of non-Christian Jewish sectarians with a comparable outlook, and a syncretism or amalgam that was partly Jewish (and perhaps Essene), partly pagan, partly Christian is not surprising in Asia Minor.

The reply in Colossians to this false teaching is specially notable for its daringly high claims for Christ, relating him to all creation as its agent or medium, its goal and its reconciler (i, 15-17, 19), and to the church as its head and reconciler (i, 18, 21). Christ is called God's "mystery" (Gr. *mysterion*, ii, 2; cf. i, 27; that is, God's secret plan now divulged), and in Christ the "entirety" or "fulness" (Gr. *pleroma*) of the Godhead is said to dwell (i, 19; ii, 9). He is "first-born of all creation" (i, 15; i.e., in view of the consistent attitude of the New Testament, God's unique Son, prior to creation). Consequently, whatever reality or status may be accorded to the angelic powers ("thrones," "dominions," "principalities," "authorities," etc., i, 16 etc.), they are subordinate to Christ. To be incorporated in him is to be complete (ii, 9 ff.). Ascetic practices and a cult of angels are at best irrelevant (ii, 16 ff.). Thus, a supreme and cosmic position is more explicitly assigned to Christ here than in any epistle that is probably earlier (though cf. I Cor. viii, 6). Correspondingly, *ecclesia* is used of the universal church in Col. i, 18, 24 (as in Ephesians), although in iv, 15 (cf. Philem. 2) it is still used for the local congregation.

**Instruction on Christian Conduct.**—This vigorous doctrinal polemic is followed (ii, 20-iv, 6) by a noble treatment of the status of Christians and of the qualities of character and conduct following from the acceptance of Christ and incorporation in him by baptism. This includes (iii, 18 ff.) a Christian form of such household instructions as, in Jewish and pagan form, figure also in contemporary literature; and the most striking contrast which it presents when compared with non-Christian parallels is in the recognition of the reciprocity of the duties—husbands owing a duty to wives, parents to children, masters to slaves, as well as vice versa. And all is lifted to that level of relationship described as "in the Lord."

The letter closes (iv, 7-18), as it began (see i, 1 ff., which includes a magnificent prayer), with personal messages, injunctions and greetings.

**Authorship.**—There is a close relationship between Colossians and Ephesians (*q.v.*); and, despite certain opinions to the contrary, the balance of probability seems to favour the priority of Colossians, if either is derived from the other. Although the Paulinity of Ephesians is doubtful, that of Colossians is less vulnerable. Its genuineness, in whole or part, has nevertheless often been questioned by scholars, beginning at least as early as E. T. Meyerhof (1838).

The chief ground for doubt is the "advanced" or "high" Christology. But there is nothing here incompatible with assured Pauline thought, and the explicitness of the statements may be attributed to the situation addressed. As for vocabulary, the absence of certain terms familiar from other Pauline Epistles and the presence or particular use of certain others are not conclusive. Most of the Epistles are written to special situations, and their vocabulary is in part conditioned by this. And that there is no reference to "justification by faith" need only mean that this was not, at that moment, the particular issue. The style of writing, again, is an uncertain guide, especially where different amanuenses, with varying degrees of freedom, may be concerned.

In favour of genuineness is the fact that the Epistle to Philemon (*q.v.*), which is obviously genuine, coheres so closely with Colossians that it is difficult to accept the one and reject the other.

**Date.**—The date and circumstances of the imprisonment in question are debated. Until modern times it was generally assumed that the "captivity Epistles" were all written by Paul from Rome (see Acts xxviii, 16), that is, c. A.D. 62, but earlier imprison-

ments have been suggested by modern scholars. Acts xxiii, 35; xxiv, 27 indicates a prolonged imprisonment at Caesarea, and the presence of Aristarchus (Col. iv, 10) fits this period (Acts xxvii, 2). But, at Caesarea, expectation of release (Phil. i, 25; Philem. 22) could only have meant expectation of lynching (Acts xxiii, 12 ff.; xxv, 3), which renders the Caesarean hypothesis doubtful. Others postulate an imprisonment at Ephesus during the period covered by Acts xix (for although Acts here mentions no imprisonment, II Cor. xi, 23 ff. seems to demonstrate that Acts is not exhaustive). Advocates of this hypothesis appeal to affinities between the captivity Epistles and the Romans-Corinthians group; to the improbability of Paul's asking for hospitality at Colossae (Philem. 22) if he were far away in Rome; to the fact that in the "Marcionite prologues" (early introductions to the New Testament books, perhaps connected with the 2nd-century heretic Marcion) Colossians is described as written by the apostle from Ephesus; even, that tourists are still shown the "prison of Paul" among the ruins of Ephesus. But the latter is scarcely serious evidence, and the prologue is curiously worded (why is Paul described as *iam ligatus*, "already a prisoner?") and in any case the prologue to Philemon places that letter at Rome. Besides, Mark and Luke (Col. iv, 10, 14; Philem. 24) are not known to have been with Paul at Ephesus. Thus, the case against the Roman origin is not decisive; and although the allusions in Phil. i, 13 and iv, 22 to the *praetorium* and to the emperor's "household" have been shown to be possible in the provinces, they certainly fit Rome equally well if not better. But the "captivity Epistles" are, of course, not necessarily homogeneous in time and occasion, and the data are insufficient for certainty. Chronological arguments from style and contents are particularly precarious. Fortunately, date and place are in this case less vital than the doctrinal and ethical contents of the Epistle.

**COLOSSUS** is a statue considerably larger than life-size. In Egypt and Mesopotamia, in particular, colossal statues were in favour in antiquity. The famous Egyptian sphinx, still to be seen near the pyramids at Gizeh, is about 240 ft. long, and the statue of Ramses II in the Ramesseum was originally perhaps 57 ft. high. Herodotus, visiting Egypt in the 5th century B.C., constantly refers to such gigantic statues as *colossoi*. Likewise, in India, China and Japan, colossal figures of deities were placed inside pagodas.

When the Greeks in the 7th century B.C. began to produce monumental sculpture, they too created colossal figures. The archaic Apollo of Delos, generally referred to as the Delos colossus, was four times life-size; fragments of archaic statues three times life-size have been unearthed at Samos; and the throne of Apollo at Amyclae, by the sculptor Bathycles, described at length by Pausanias, supported a primitive wooden statue about 45 ft. high. Though in the subsequent periods the scale diminished and life-

size sculpture became the norm, admiration for the colossal persisted. Phidias' chryselephantine statues of Athena Parthenos and the Zeus at Olympia were about six and seven times life-size, respectively.

The most famous colossus of all was the bronze statue of Helios in Rhodes, the work of Chares, a pupil of Lysippus. It was over 100 ft. high, took 12 years to complete and was considered one of the seven wonders of the world. After 56 years, it was overthrown by an earthquake (c. 224 B.C.), and it lay on the ground for centuries, until the pieces were sold and carried off in A.D. 653.

All over the Roman empire colossal statues of deities and emperors were erected to impress the might of Rome on the people. According to Pliny, Zenodorus, after having made a colossal statue of Hermes in Gaul, was summoned by Nero to Rome and there made a statue 106 ft. high, intended to represent that emperor but later dedicated to the sun. A Jupiter erected on the Capitoline hill is said to have been visible from Monte Albano.

The taste for colossal sculpture has never died out. It persisted through medieval times (a St. Christopher about 28 ft. high was placed at the entrance of Notre Dame), and continued through the Renaissance (cf. the statues by Michelangelo and Giovanni da Bologna) to the present time. The "Christ of the Andes," standing on the border of Argentina and Chile, is 26 ft. high; the "Bavaria" (Munich) by L. M. Schwanthaler is about 60 ft. high; the "France" ("Le Puy") by J. M. Bonnassieux is about 50 ft.; and the statue of "Liberty Enlightening the World" by F. A. Bartholdi, standing in New York harbour, attains, with torch and pedestal, a height of about 305 ft. Finally, the rock-cut portraits of Washington, Jefferson, Lincoln and Theodore Roosevelt by Gutzon Borglum, in the Black hills of South Dakota, measure 60 ft. from crown to chin. (G. M. A. R.)

**COLOUR.** Even casual observation indicates that an understanding of colour involves not only physics but physiology and psychology as well. As a matter of common experience, a white tablecloth appears to be just as white under candlelight as it does under daylight, despite the fact that the light reflected by the tablecloth into the observer's eye is actually as yellow as the candle flame itself. The failure to perceive the cloth as yellow is the result of a tacit assumption by the brain concerning the constancy of the physical characteristics of things. Thus, an object at five feet does not appear to be twice as large as when it is ten feet away, although the linear dimensions of the image on the retina of the observer's eye are actually twice as large. Instead, the brain perceives the size of the object to be constant, after correcting the initial perception for the distance of the object. In much the same way, the colour of an object in daylight is intuitively regarded as one of its physical characteristics, and the brain corrects for the conditions of illumination whenever correction is necessary and possible.

**The Physical Approach.**—Colour has been used for decorative purposes since prehistoric times, but it was not until 1666 that a systematic investigation of its nature was undertaken. In that year, Sir Isaac Newton, then only 23, began a long series of experiments that provided the foundation for our modern knowledge. In the first experiments, Newton placed a glass prism in a beam of sunlight which entered a darkened room through a small hole in the shutter, thus producing the red, orange, yellow, green, blue, indigo and violet of the familiar solar spectrum. This dispersion of light by a prism to form a spectrum had been observed before, but Newton was the first to perform the additional experiment of recombining the spectrum colours by means of a lens or a second prism. The fact that white light was produced by the recombination led Newton to conclude that all the spectrum colours had been present in the original beam.

Newton was also the first to explain what he called "the permanent colours of natural bodies." In a typical experiment, he found that both cinnabar (vermillion red) and ultramarine blue appeared red when observed in the pure red light of the spectrum, the cinnabar being the more strongly luminous of the two. In spectrally pure blue light, on the other hand, both pigments appeared blue, but the ultramarine was then the more luminous. From many

qualitative experiments of this sort, Newton concluded that bodies appear coloured under white light because they reflect some of its spectral components more strongly than others. These qualitative observations were confirmed later, after instruments called spectrophotometers had been developed for measuring the reflectance of a surface as it is illuminated in turn by all the visible components of white light.

**Spectrophotometry.**—A typical procedure in spectrophotometry is to disperse the white light from a suitable source into a spectrum and then to isolate a narrow spectral band by means of a slit placed in the plane where the spectrum comes to focus. The light passing through this slit is split into two beams, one of which falls on the sample under investigation and the other on a standard white surface that is known to reflect substantially all the light that falls upon it. The sample, being a poorer reflector of light than the white standard, will be correspondingly less luminous; and the luminance ratio is readily found by the application of any adequate photometric technique. This ratio is the spectral reflectance of the sample for light in the spectral region employed. For colorimetric purposes, the above procedure is repeated with the slit in a different position each time until the sample has been subjected to examination throughout the entire range of the visible spectrum. Ordinarily, it is quite sufficient if the spectral reflectance of the sample is determined at wave-length intervals of 10 m $\mu$  (1 m $\mu$  = 0.000001 cm.), in which case a total of 31 separate measurements suffices to cover the range from 400 m $\mu$  in the violet to 700 m $\mu$  in the red.

For obvious reasons, the results of such an analysis are usually represented graphically, as is done in fig. 1 for an artist's pigment (emerald green). This spectral reflectance curve shows that emerald green is a poor reflector of violet light (400 m $\mu$  to 450 m $\mu$ ), an increasingly better reflector of blue light (450 m $\mu$  to 500 m $\mu$ ), has a maximum of reflectance for green light (500 m $\mu$  to 570 m $\mu$ ), and becomes a progressively poorer reflector of yellow light (570 m $\mu$  to 590 m $\mu$ ), orange light (590 m $\mu$  to 610 m $\mu$ ), red light (610 m $\mu$  to 700 m $\mu$ ).

As the curve indicates, when the sample is illuminated by ordinary white light, the reflected light is predominantly green.

The concepts of spectrophotometry, although dating from the time of Newton, were not embodied in physical instruments until the second half of the 19th century, when a number of types appeared in rather rapid succession. However, these instruments had little influence on the development of the techniques of colour measurement, partly because they were intended primarily for the spectrophotometry of light sources or transparent materials and partly because even a single analysis was a tedious and time-consuming procedure.

FIG. 1.—SPECTRAL REFLECTANCE CURVE OF AN ARTIST'S PIGMENT

In 1928, at Massachusetts Institute of Technology, A. C. Hardy constructed an instrument designed especially for the rapid routine analysis of opaque samples. The human eye was replaced by a phototube, and the instrument was made completely automatic, even to the drawing of the spectral reflectance curve of the sample on suitably prepared graph paper. Introduction of this instrument into a variety of industries led to the formal recognition of the spectrophotometer "as the basic instrument in the fundamental standardization of colour" (American Standards Assn., 1942).

**Colorimetry.**—Although spectrophotometry provides an adequate description of the colour of a surface when illuminated by spectrally pure (homogeneous) light of any wave length, it does not adequately indicate the colour under a heterogeneous mixture, such as daylight. Many instruments have been developed that do evaluate the colour of a surface under heterogeneous illumination, and, as a class, they are known as colorimeters. In a typical in-

strument, one half the field of view is occupied by the sample, illuminated in the desired manner. The other half is a comparison field whose colour can be altered by the observer until a colour match with the sample is established. In a colorimeter of the trichromatic type, the comparison field contains a mixture of red light, green light and blue light, the amounts of which can be varied independently. Inasmuch as only one setting for each of the three controls will produce a match with a given sample, the colour of the sample is indicated by the amounts of the three primaries employed in making the match. Such primaries are often called basic stimuli, and the colour of the sample is therefore said to be specified by its tristimulus values. (See below for distinction between additive and subtractive primaries.)

Colorimeters are not so useful as the simplicity of this procedure suggests because the two halves of the photometric field will ordinarily be different in spectral composition. For example, the primaries might be a spectrally pure red, green and blue; whereas, if the sample is the emerald green of fig. 1, it will, when illuminated by daylight (or its equivalent), reflect some light at all wave lengths. Although any person with normal colour vision experiences no difficulty in matching the two halves of the field under such circumstances, two substantially normal persons may require slightly different amounts of the three primaries to produce a match. These small individual differences are nevertheless large enough to cause measurements made with a colorimeter to be uncertain by an amount that is greater than the colour difference that can be easily observed in a direct side-by-side comparison of two samples. Attempts have been made to replace the eye by phototubes, or by other physical detectors, but even these devices have been unable to meet the exacting requirements when the comparison involves large differences in spectral composition.

**The Indirect Method of Colorimetry.**—It is always possible to obtain the required accuracy with a colorimeter by using a large group of observers and averaging their results. Because this procedure does not lend itself to routine testing, an indirect method of colorimetry is ordinarily employed. The basis for this method was established about 1860 by James Clerk Maxwell, who evaluated the spectrum colours in terms of three arbitrarily selected primaries. Such measurements were subsequently repeated on several occasions, but the first systematic investigations, using large groups of normal observers, were made in England about 1928 by W. D. Wright and by J. Guild. Their combined results are indicated in abridged form in Table I after transformation to the same convenient set of primaries. In terms of these primaries, a unit amount of radiant energy having, for example, a wave length of 400 m $\mu$  is seen to be visually equivalent to a mixture comprising 14.3 units of the red primary, 0.4 units of the green primary and 67.9 units of the blue primary. Thus, the table indicates the tristimulus values of unit amounts of the various spectrum colours.

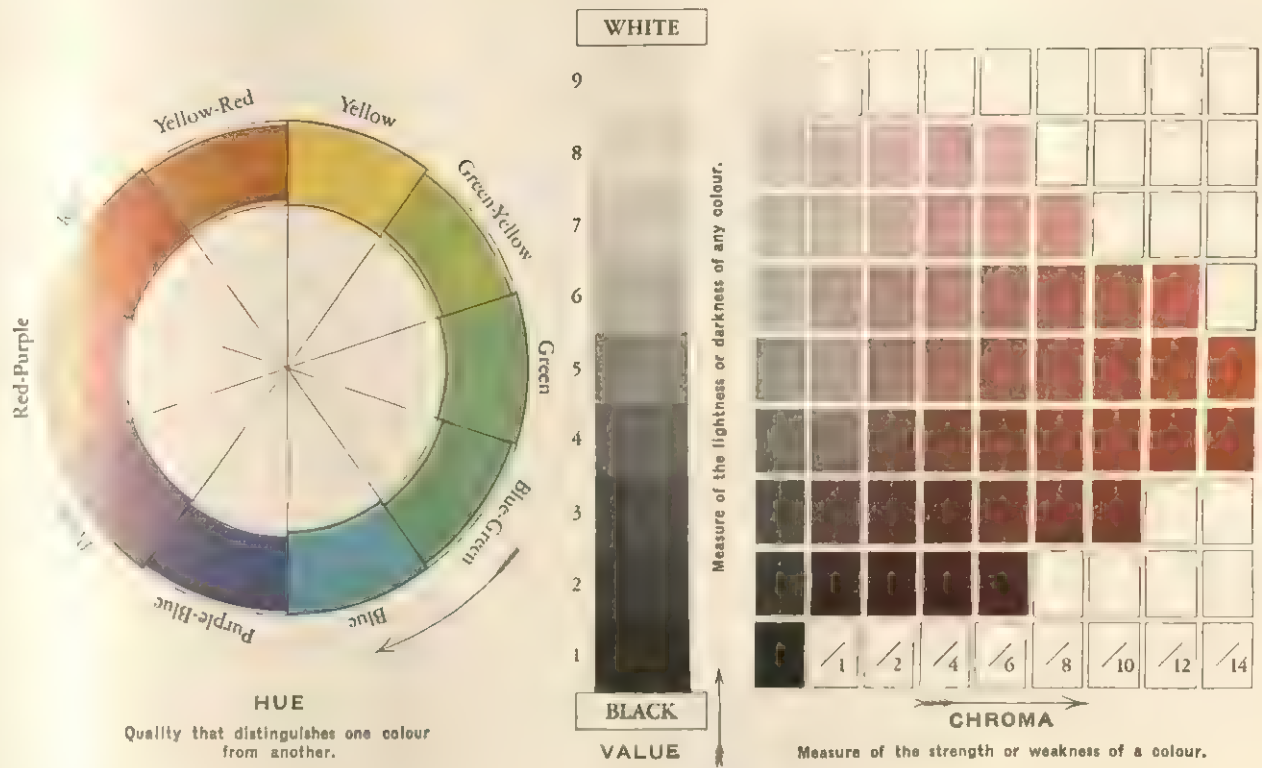

TABLE I.—Tristimulus Values of the Spectrum Colours\*

Wave length (m $\mu$ )	X (red)	Y (green)	Z (blue)
400	14.3	0.4	67.9
420	13.4	4.0	64.6
440	34.3	23.0	17.7
460	290.8	60.0	3669.3
480	95.6	139.0	811.0
500	4.9	233.0	273.2
520	63.3	710.0	73.2
540	290.4	954.0	30.3
560	504.5	995.0	3.9
580	916.3	870.0	1.7
600	1062.2	631.0	0.8
620	854.4	381.0	0.2
640	447.9	175.0	...
660	164.9	61.0	...
680	46.8	17.0	...
700	11.4	4.1	...

\*Adopted by International Commission on Illumination, 1931.

Data of this type form the basis for the indirect method of colorimetry because, given the tristimulus values for a unit amount of light of any wave length, the tristimulus values of any heterogeneous mixture of known spectral composition can be readily computed by a simple process of summation. Since the spectral composition of the heterogeneous light reflected by a given sample under a given illuminant is determined by its spectrophotometric

At the right is a projection showing the Principal and Intermediate Hues arranged radially in ten equal divisions about the vertical scale of Value in the same order as the Hue circle above. For sim-

plicity, Hues are shown only at the Value in which they reach their strongest Chroma. A complete Tree would show each Hue developed completely from black to white, as shown in the red Chroma chart above.

Example 1

The magenta pattern rotated through  $30^\circ$  and printed over the yellow pattern producing four colours

### A THREE-COLOUR SUBTRACTIVE PROCESS IN COLOUR REPRODUCTION

characteristics, one can compute tristimulus values from spectrophotometric data without having to use a colorimeter. In effect, one hypothesizes a colorimeter employing the standard set of primaries and then determines by computation what the tristimulus values would be in a given case if the observers of Wright and Guild were to use the hypothesized colorimeter under the same carefully controlled conditions.

In 1931 the International Commission on Illumination or Commission Internationale de l'Éclairage (C.I.E.) defined the standard observer for colorimetry by officially adopting the data of Wright and Guild, and this hypothetical observer subsequently took part in countless colorimetric determinations throughout the civilized world.

At the same time, the C.I.E. recommended three standard illuminants for actual use with a colorimeter or for hypothesization when the indirect method is employed. Illuminant *A* was intended to be typical of the light from an ordinary gas-filled tungsten lamp, illuminant *B* to represent noon sunlight and illuminant *C* to represent average daylight. Of these three standard illuminants, illuminant *C* came into far greater use than did the others, especially in the United States. In 1942 the American Standards association recommended that, "In the absence of a special reason for adopting some other illuminant in reducing spectrophotometric data, the standard C.I.E. illuminant *C*, representative of average daylight, shall be used." In terms of this U.S. standard method of colour specification, the tristimulus values of the emerald green sample whose spectrophotometric curve is reproduced in fig. 1 are found by calculation to be  $X=22.7$ ,  $Y=39.1$  and  $Z=31.0$ .

**Dominant Wave Length, Reflectance and Purity.**—Although three tristimulus values provide a basic colour specification, it is common practice to translate them into a numerical language that is more interpretive. This translation is facilitated by the fact that the basic stimuli of the C.I.E. system were purposely so selected that, in the proper units, the value of *Y* indicates the reflectance of the sample in the ordinary photometric sense. That is, the emerald green sample of fig. 1 is only 39.1% as luminous as the standard white surface when both are illuminated equally by average daylight. The neutral colours (white, gray and black) are adequately specified by this single number, provided they are truly neutral, or achromatic.

The value of *Y* represents the reflectance of the chromatic colours as well, but it is then necessary to specify the quality of the reflected light as well as its quantity. The standard method of specifying the quality, or chromaticity, is based on the principle of the so-called monochromatic colorimeter, in which the comparison field is occupied, not by a mixture of three primaries, but by a mixture of white light and homogeneous light. Every colour (except purple) can be matched in the comparison field of this type of colorimeter by adding an appropriate amount of white light to an appropriate amount of homogeneous light of the proper wave length. The wave length of the homogeneous light is then known as the dominant wave length of the sample.

In practice, monochromatic colorimeters are almost never used because the indirect method is vastly more satisfactory. Tables and charts have been prepared which, for the assumed standard conditions, enable the dominant wave length of the sample to be readily determined from its tristimulus values. In the case of the above sample of emerald green, the dominant wave length is found by this method to be 511.9 mμ. It will be noted that the dominant wave length is not the wave length at which the spectrophotometric curve has its maximum; although, in the case of this particular sample, it is not very different.

Purples and other nonspectral colours are generally characterized by spectrophotometric curves having two maxima, one at the violet end of the spectrum and the other at the red end. When such samples are illuminated by daylight, they reflect a mixture of red light and violet light that cannot be matched by a mixture of white light and any single band of homogeneous light. Hence, in measuring nonspectral colours with a monochromatic colorimeter, green light is added to the sample side of the field until a match is produced with the white light in the comparison field.

TABLE II.—Analysis of Artists' Pigments

Pigment	Dominant wave length (millimicrons)	Reflectance (percent)	Purity (percent)
Alizarin crimson	628.0	6.6	57.2
English vermilion	608.1	22.3	59.9
Cadmium red	604.8	20.8	67.3
Venetian red	590.2	13.1	50.2
Burnt sienna	598.5	7.6	40.1
Burnt umber	580.5	5.2	34.2
Cadmium orange, medium	586.0	42.2	86.0
Raw sienna	584.2	20.0	61.3
Chrome yellow, medium	581.6	63.1	81.8
Zinc yellow	575.8	32.6	79.7
Zinc white	560.5	94.9	1.5
Chrome green, medium	552.4	16.0	34.7
Emerald green	511.9	39.1	22.8
Ivory black	494.5	2.2	1.7
Cobalt blue	474.6	16.8	65.5
Cobalt violet	560.3a	9.3	48.5
Manganese violet	553.7a	27.0	21.6

From "Technical Studies," Fogg Art Museum; Harvard University (Cambridge, Mass., 1939).

This addition of green light to the sample field is the equivalent of subtraction from the white light of the comparison field. The green light is therefore complementary (in the ordinary sense of complementary colours) to the mixture of red light and violet light that would need to be added to the comparison field if the match were to be produced by the ordinary procedure. Thus, the artist's pigment known as cobalt violet is found by these standard procedures to be a bluish-purple whose dominant wave length is 563.5a, the subscript indicating that the complementary wave length is being specified.

Although two samples may be alike in both dominant wave length and reflectance, they may nevertheless be unlike in another respect. One sample may be nearly gray in appearance while the other may be strongly chromatic. This third attribute is called purity. Like dominant wave length, the numerical value of the purity is ordinarily ascertained from its tristimulus values by the aid of appropriate tables or charts. The standard practice is to represent purity on a scale that assigns zero purity to the achromatic colours (white, gray and black) and 100% purity to the strongest colours that are theoretically possible at each dominant wave length; i.e., the spectrum colours themselves. On this standard scale, the emerald green sample of fig. 1 is found to have a purity of 22.8%.

As an aid to the interpretation of the significance of this standard method of colour specification, Table II is reprinted in abridged form from a study of artists' pigments published for the Fogg Art Museum of Harvard University. The pigments have been arranged, for convenience, in the order of decreasing dominant wave length, with the nonspectral colours at the bottom. It will be seen, for example, that Venetian red is somewhat more orange than cadmium red, that it is the darker of the two, whereas the cadmium red is the stronger (purer). One wishes that the colours of the pigments used by the old masters might have been thus preserved forever in terms of objective physical measurements.

**Graphical Representation.**—For the same reason that the study of geography is facilitated by the use of maps, a graphical method of representing colour is desirable. The analogy is particularly apt because three parameters are required to describe either a colour or the location of a point in space. The customary procedure in colorimetry is to represent the quality of a colour on a two-dimensional diagram, its quantity being amply indicated by its *Y* tristimulus value. In the type of chromaticity diagram that has become standard through extensive use, the quality of a colour is specified by its trichromatic coefficients, which are defined in terms of its tristimulus values by the following equations:

$$x = \frac{X}{X+Y+Z}$$

$$y = \frac{Y}{X+Y+Z}$$

$$z = \frac{Z}{X+Y+Z}$$

It follows from this definition that  $x+y+z=1$ , for all values of

$X$ ,  $Y$  and  $Z$ . Because of this relationship, chromaticity is adequately expressed by any pair of trichromatic coefficients; and the standard practice is to employ  $x$  and  $y$ .

The locus of the spectrum colours on the standard diagram is shown by the solid line in fig. 2. This locus is constructed by

FIG. 2.—STANDARD CHROMATICITY DIAGRAM

An extension of this procedure enables the entire spectrum locus to be constructed.

If spectrum light whose wave length is 400  $m\mu$  be mixed with spectrum light whose wave length is 700  $m\mu$ , the resultant colour can be shown to lie along the dashed line of fig. 2 connecting the two points, the exact position in the line being dependent upon the proportions of each in the mixture. Since this is a general property of the chromaticity diagram, it follows that the point representing the additive mixture of any number of spectrum colours in any proportions, and hence all real colours, must always lie within the area bounded by the spectrum locus and the dashed line joining its ends. In particular, the mixture selected as the standard of average daylight (illuminant  $C$ ) is found by the summation process referred to above to be represented by the point  $C$  near the centre of this area. A pure white reflecting surface under this illuminant is likewise represented by the point  $C$ .

The chromaticity diagram facilitates a better understanding of the concepts of dominant wave length and purity discussed in the preceding section. In fig. 3, the point  $G$  represents the trichromatic coefficients  $x=0.2446$  and  $y=0.4214$  of the emerald green sample whose tristimulus values were previously found to be  $X=22.7$ ,  $Y=39.1$  and  $Z=31.0$ . This point is seen to lie on a line connecting the white point  $C$  with a point on the spectrum locus at 511.9  $m\mu$ , and it will be recalled that this was the dominant wave length of the emerald green sample. The purity of this sample was previously found to be 22.8%, and this attribute is represented by the relative distance of the point  $G$  from the white point  $C$ .

Since all neutral grays have the same trichromatic coefficients as a white surface and differ from it only in reflectance, they are all represented by the point  $C$  on this type of diagram.

The problem of graphically representing reflectance is akin to that of representing elevation on the ordinary map. One may imagine that surfaces of zero reflectance are represented by points in the plane of the chromaticity diagram; and that, in a three-dimensional diagram, reflectance would be represented by the height of a point above this plane. David L. MacAdam investigated the theoretical boundaries of the colour space thus defined by the C.I.E. chromaticity diagram. In practice, of course, these boundaries are set by the characteristics of the available dyes and

pigments, and the boundaries are extended from time to time as new colorants are discovered. MacAdam, ignoring these essentially chemical limitations, calculated the theoretical limits that may some day be approached but never exceeded. Thus, each contour line in fig. 4 defines an area within which all colours having

FIG. 4.—MAXIMUM ATTAINABLE REFLECTANCE FOR SPECIFIED CHROMATICITY

the indicated reflectance must inevitably be found, assuming no fluorescence. It is seen at once that any surface reflecting as much as 90% of the white light incident upon it must be either a yellowish-green or a near-white. It will also be seen that a strong blue must inevitably be a dark colour. To manufacturers of dyes and pigments, the shape of this colour solid is important because, when the available colours are plotted on this diagram, the regions of potentially profitable research on new colours are clearly indicated.

#### Material Colour Standards.

—The concept of complete interchangeability of parts, which forms the basis of all mass-production industries, introduced a new era in which the public came to expect the colour of any product to be maintained constant within narrow limits. Prior to the development of adequate colorimetric techniques, the colour had perforce to be maintained by means of reference standards, often over long periods of time. This method presented no real difficulties in industries like the ceramic industry where the products are so permanent in their colour characteristics that samples from the production line can be set aside for use as reference standards. In many other industries, however, a sample of the product may be quite unsatisfactory for this purpose. In any case, a growing collection of reference standards, accumulated at random, generally becomes unwieldy beyond a certain size because of its lack of organization.

It is not unnatural that there should have been many attempts to construct colour systems by organizing collections of material standards in accordance with some logical plan. Of the various systems of this sort, the most successful was that originated by A. H. Munsell, who prepared and issued the *Atlas of the Munsell Color System* in 1915. Munsell's three parameters, hue, value and chroma (figs. 5, 6 and 7), corresponded to the basic parameters, dominant wave length, reflectance and purity. The Munsell value scale divided the range between a perfect black and a perfect white into ten steps, spaced in accordance with the readings of a photometer that Munsell had constructed. This photometer contained a cat's-eye shutter, and, as a consequence, value in the original Munsell system was equal to the square root of the reflectance in the basic system. Thus, a surface of value 5 has a reflectance of 25%.

With the value scale established, Munsell selected samples of red, yellow, green, blue and purple at value 5 which appeared to be equidistant from a gray of

FIG. 5.—MUNSELL'S PARAMETER HUE

the same value and from one another. These became the principal hues of the system. The five intermediate hues which completed the hue circuit are the complements of the principal hues. By definition, these principal hues and their intermediates were arbitrarily said to be of chroma 5. The several hundred colour chips of the *Atlas* are small rectangular slips of paper painted with water-colour paints of considerable permanence. All the chips in a horizontal row have the same value and all those in a

vertical column have the same chroma. The entire system was constructed in accordance with rules of disk mixture (*see below*).

The colour tree of Munsell is a three-dimensional representation of this system in cylindrical co-ordinates with the scale of neutral values as the vertical axis. Hue is represented by points of the compass around the vertical axis; chroma by distances from this neutral axis. For each hue, the maximum chroma at any value level was limited by available pigments with suitable permanence. In 1939, J. Tyler, by using MacAdam's colour solid, computed the maximum chroma theoretically possible at each hue and value.

After Munsell's death, a new edition of the *Atlas*, the *Munsell Book of Color*, was issued in 1929. Superficially, the two editions are strikingly similar; but the philosophies underlying their construction were different. The nature of this difference will be clear from a consideration of the value scale of the original system. If Munsell had divided the range between black and white into equal steps of reflectance instead of into equal steps on a square-root scale, the chips would have appeared to be spaced too closely in the upper range and too far apart in the lower range. Psychologists have long recognized three attributes of a colour sensation: hue, brightness and saturation; and, by definition, the steps of a psychological scale appear to be equally spaced. The value scale of the *Atlas* approximates a psychological brightness scale, but the value scale of the *Munsell Book of Color* is a closer approximation. Each system has its advantages. Thus, the chips of the *Atlas* were assigned positions in the system in accordance with certain fixed rules; whereas the chips of the *Book of Color* were intended to be per-

tion on this diagram shows that the emerald green sample of fig. 1 has a hue designated by 5.0G, the symbol 5.0 indicating that the hue of the sample is the same as that of the primary green hue of the system. Its value is found to be 6.7; its chroma, 11.2. In the standard method of notation, the colour of this sample of emerald green would be written 5.0G 6.7/11.2.

The use of any system of material standards requires taking precautions that are often ignored. Frequently the spectral reflection characteristics of the sample are so unlike those of the chips used as reference standards that the match is meaningless unless made by a normal observer under a standard illuminant. Also, because of possible differences in surface characteristics, the geometrical mode of illumination and observation must be standardized; e.g., the colour chips of the *Munsell Book of Color* have nearly matte surfaces, and their appearance is only slightly affected by the mode of illumination and the mode of observation. On the other hand, since the appearance of a glossy sample varies with the mode of illumination and observation, its comparison with the Munsell chips must be made under standard viewing conditions. Similar considerations apply to the mode of illumination and observation used in spectrophotometers and colorimeters, but standard conditions are then more likely to be maintained because they are fixed by the design of the instruments. Space does not permit discussion of other colour systems, as those of R. Ridgway, W. Ostwald and others. The significant fact is that chips of any system of material standards can be evaluated in terms of the basic system by standard procedures, thus making the basic system the common language into which all others can be translated. In this way, all systems can be interrelated; a colour specification in one system can be translated into any other.

**The Colour of Light Sources.**—It will be obvious that the colorimetric techniques described in earlier sections of this article can be adapted to the evaluation of the colour of a light source. Television is one field in which these techniques are particularly appropriate because the television screen is a primary source whose colour *per se* is of some importance. Ordinarily, however, a light source is used to provide illumination, and the colour of the source is then of lesser importance than the colour of objects illuminated by it.

It was pointed out in the opening paragraph of this article that a tablecloth may look just as white by candlelight as it does by daylight, and this example of the psychological principle of colour constancy would seem to indicate that the spectral composition of the source is not of great importance. The fact is that the principle itself is not of general applicability, as can be deduced on logical grounds from the behaviour of two samples that match under daylight but fail to match under some other source. Evidently, the colour of both samples does not remain constant under changing illumination. If those who select the dyes and pigments that are used in producing the colours encountered in everyday life were not influenced by the desires of the consuming public, colour constancy might be the exception rather than the rule. For example, when dyeing a textile fabric green, the dyer will normally formulate the dye bath so as to produce a fabric that appears green under artificial light as well as under daylight. He could, however, by a different choice of dyes, produce a fabric which, although green by daylight, is a reddish brown under tungsten light. Thus, the principle of colour constancy derives much of its justification from the circumstance that inconstant colours are regarded by the public as freakish.

If two samples are identical in their surface characteristics and are also identical in their spectrophotometric characteristics, they are physically similar and will always be considered a perfect match under any illuminant. If the two samples are unlike in their spectrophotometric characteristics, they may nevertheless be a colour match under some illuminant. In this case, they will not ordinarily match under an illuminant of different spectral composition, even when the second illuminant appears to have the same colour as the first. It is more important to know the spectral composition of the light emitted by a source, as determined by a spectroradiometer, than it is to know its colour, as determined (directly or indirectly) by a colorimeter.

FIG. 6.—MUNSELL'S PARAMETER VALUE

FIG. 7.—MUNSELL'S PARAMETER CHROMA

ceptually uniform in spacing, under standard viewing conditions.

In 1935 J. J. Glenn and J. T. Killian analyzed all the chips of the *Munsell Book of Color*, determining the dominant wave length, reflectance and purity of each. In 1942 the American Standards association recommended the use of the *Munsell Book of Color* whenever applicable to the specification of the colour of surfaces. Approximate identifications of Munsell hue, value and chroma are secured by direct visual comparison with the chips themselves. For more accurate Munsell notations, it was recommended that the Munsell notation be determined by using the basic method and a special chromaticity diagram prepared by direction of the Colorimetry committee of the Optical Society of America. Interpol-

Before the introduction of fluorescent lighting, tungsten lamps were the principal sources of artificial illumination. When the temperature of a tungsten filament is increased, its colour changes from red through orange to a pale yellow. From theoretical studies of the behaviour of ideal radiators, it is known that, if the temperature of a tungsten filament could be indefinitely increased, the colour of the filament would become white and finally blue.

Because the laws pertaining to the behaviour of ideal radiators are so well known, the colour of such a radiator at any temperature can be readily calculated by the indirect method of colorimetry. A tungsten lamp does not radiate so much energy as an ideal radiator at the same temperature, but its spectral quality is not very different. For this reason, it is common practice to specify the colour of a tungsten lamp in terms of its colour temperature, which is, by definition, the temperature of an ideal radiator of the same chromaticity. The concept of colour temperature can often be extended to sources whose colour is not a function of temperature. Thus, the colour temperature of blue sky is frequently in the neighbourhood of  $20,000^\circ$  on the Kelvin scale, the use of the concept being justified in this case because the spectral quality of sky light is a reasonably close approximation to that of an ideal radiator at this temperature.

**The Colour of Transparent Materials.**—Until now, we have been concerned with samples that were assumed to be opaque, but the techniques of colour measurement discussed above are applicable, with minor modifications, to the measurement of the colour of transparent materials, such as a sheet of coloured glass or coloured plastic. Thus, by means of a spectrophotometer, the spectral transmittance of a sample can be determined at convenient wave-length intervals throughout the visible spectrum, the spectral transmittance at any wave length being the ratio of the amount of light transmitted by the sample to the amount of light incident upon it. Colorimeters can likewise be used in a direct evaluation of the colour of the sample when it is placed in a beam of heterogeneous light, or the indirect method of colorimetry may be employed. Systems of material standards have also been developed, and the series of coloured glasses prepared for use with the Lovibond tintometer deserves special mention.

When the thickness of a coloured material is varied, its spectral transmittance curve changes shape in a manner that can be calculated by the application of Bouguer's law, after correction is made for the reflection losses at the two surfaces of the sample. Bouguer's law states that  $t = t_0^x$ , where, at any wave length,  $t$  is the spectral transmittance of a thickness  $x$  and  $t_0$  is the spectral transmittance of a unit thickness. Thus, if a unit thickness of the sample transmits 10% of the incident light at some wave length, doubling the thickness will result in a transmittance of  $(10\%)^2 = 1\%$ . If at some other wave length, a unit thickness transmits 90% of the incident light, doubling the thickness will reduce the transmittance to  $(90\%)^2 = 81\%$ .

Because a given increase in the thickness of the sample causes a greater reduction in transmittance in spectral regions where the transmittance of a unit thickness is low than it does in spectral regions where the transmittance of a unit thickness is high, varying the thickness of the sample sometimes causes surprising changes in colour. A common illustration is provided by certain green eyeshades which contain a dye whose spectral transmittance may be not more than 30% for green light and even less elsewhere, except in the far red, where the transmittance may increase abruptly to a value approaching 100%. Because of the vastly greater sensitivity of the eye near the middle of the visible spectrum, the eyeshade appears green. The effect of increasing the thickness of the material is easily observed by folding it in such a manner that the light must pass through two or more layers. By thus increasing the length of the optical path through the material, the transmittance for green light is decreased more than the transmittance for red light; and, at some length of optical path, the dominant wave length shifts abruptly from green to red. This phenomenon, called dichromatism, was surrounded for many years by an aura of mystery before it was seen to be a direct consequence of Bouguer's law.

When a liquid, such as a dye solution, is contained in a glass

cell having parallel sides, it is ordinarily of interest to know how the shape of the spectral transmittance curve will vary with the concentration of the solution. If only a single substance is present, Beer's law states that  $t = t_0^c$ , where  $t$  at any wave length is the spectral transmittance for a concentration  $c$  and  $t_0$  is the spectral transmittance for unit concentration. This law holds also for a mixture of substances, provided no chemical reactions take place. Thus, although it is often stated that some substances do not obey Beer's law, such substances are invariably mixtures of two or more components in an equilibrium that depends upon the concentration. It will be seen that, when no such equilibrium is involved, varying the concentration produces the same change in colour as varying the length of the optical path.

**The Optical Mechanism of Colour Production.**—The brilliant colours produced by a prism or diffraction grating, by the interference of light or by polarization are the result of optical phenomena that are described elsewhere. Suffice it to say here that in all phenomena of this sort the devices employed are not themselves regarded as being coloured in the ordinary sense. This is presumably so because these devices merely separate white light into components which, although deviated in different directions, lose none of their original energy. Thus, the kaleidoscopic array of interference colours exhibited by a thin film of oil on the surface of water results from the fact that some components of the incident white light are reflected more copiously than others in the direction of the observer. When this oil film is observed from a different angle, the colours are seen to be different, and they may even be complementary. If it were possible for an observer to look at an oil film from all directions at once, the colour effects would disappear entirely.

By contrast, when the surface of an opaque object is viewed from different angles, the colour sensation is so nearly independent of the angle that there seems to be a reliable linkage between the stimulus and the sensation. In such circumstances, it is legitimate to regard the colour of the object as one of its inherent characteristics. This is certainly true of matte surfaces, whose appearance is exactly the same from every viewing angle. Although it is not strictly true of glossy surfaces, which, because of their smoothness, exhibit a certain amount of mirrorlike reflection, the greater abundance of nearly matte surfaces makes it convenient to regard all opaque objects as being possessed of colour, even when the colour depends to some extent on the mode of illumination and the mode of observation.

Except for metallic substances, which exhibit surface colour, the colour of an opaque object is generally a body colour. The optical mechanism involved in the production of body colour is complex, but it can be simply illustrated by reference to the colour of the sky. On a clear day, the atmosphere consists of air molecules, dust particles and water droplets, most of which are small in size by comparison with the wave length of visible light. Sunlight can pass freely through the ordinary thickness of the atmospheric layer, but the submicroscopic particles of the atmosphere scatter part of the light, and this scattering is shown by both theory and experiment to vary as the inverse fourth power of the wave length. As a consequence, violet light whose wave length is  $400 \text{ m}\mu$  is scattered about nine times more effectively than red light whose wave length is  $700 \text{ m}\mu$ . The colour of the sky is caused by this selective scattering, the scattered light reaching the observer being predominantly blue. At sunrise or at sunset, on the other hand, the light from the sun loses its short wave-length components by selective scattering before reaching the observer, and it is therefore yellow or even red. There are many days on which the size of the droplets of water suspended in the atmosphere increases steadily as the day wears on. This increase in particle size is accompanied by a loss of blue colour in the sky and by a reduction in the visibility along a horizontal path, objects even a short distance away being hidden from the observer.

Similar effects can be observed in a film of paint applied to the surface of a sheet of glass when the paint is specially compounded of submicroscopic particles of a white pigment suspended in a clear vehicle. The light reflected by the paint film when it is placed in a beam of sunlight is predominantly blue because of the selective

scattering, and the transmitted light is correspondingly deficient in blue and therefore yellowish. If the thickness of the paint film is increased, a greater proportion of the incident light is reflected by the film, and a smaller proportion is transmitted. The sun, when observed through a thick film of paint of this sort, appears as red as it does at sunset.

Evidently such a white pigment would not produce a satisfactory white paint because the particles are so small that light is easily diffracted around them. In the language of the paint industry, such a paint would be said to have little hiding power. The effect of using pigment particles of larger size is twofold; more light is scattered by each particle, and the scattering becomes less selective as to wave length. However, to obtain a maximum of hiding power, the particles should not be too large because the greater effectiveness of each particle is then more than offset by the reduction in the number of particles in a given mass of pigment. Optimum size is found to occur when the diameters of the pigment particles are, on the average, slightly less than the wave length of visible light.

The hiding power of a white paint depends not only on the particle size of the pigment but also on the relationship between the refractive index of the pigment and that of the vehicle in which the pigment particles are suspended. When the two refractive indexes are identical, light passes through the pigment particles without change in velocity, and, from an optical standpoint, the effect is the same as though the pigment particles were not present, although the viscosity and other physical characteristics of the paint are altered by the presence of the particles. To secure hiding power, pigments are selected whose indexes of refraction are high by comparison with that of the vehicle. Some forms of titanium dioxide, for example, have an index of refraction as high as 2.76; whereas the index of refraction of most vehicles is in the neighbourhood of 1.5.

Most white pigments are crystalline substances precipitated under conditions that provide for the proper control of the particle size. It is not always realized that a large crystal of the material would be as transparent as a piece of clear glass. Indeed, it often assists the understanding of the behaviour of light in a paint film to speculate that a white pigment might be produced by grinding a sheet of glass into particles so fine as to produce a powder. If the glass were perfectly transparent in sheet form, a pile of this powder would be intensely white. It could not be otherwise because, if the pile is deep enough, no light is transmitted through it; and, if the glass is perfectly clear, no light is absorbed. Hence, all the light incident upon the pile must be reflected.

These considerations aid in understanding the behaviour of coloured pigments, which, from an optical standpoint, might be prepared by crushing coloured glass until the particles are of the size required for good optical and mechanical performance as a pigment. Thus, a red pigment might be prepared by crushing a sheet of red glass which transmits red light freely while absorbing all other radiations, the latter being effectively destroyed by conversion of the energy into heat. A red pigment produced in this way would behave like a white pigment when illuminated by pure red light, but it would behave like a black pigment when illuminated by light from any other part of the visible spectrum. Selective reflection characteristics of a paint film are seen to be caused by the selective absorption that takes place within the pigment particles.

Most commercial pigments are more intensely coloured than any available coloured glass, and the latter would be said to have little tinting strength. Indeed, some commercial pigments absorb so strongly in certain spectral regions that the refractive index becomes anomalously high in those regions; and the pigment particles at or near the surface of a paint film reflect the light that would be most strongly absorbed if it could penetrate the surface of the particles. This reflected light predominates when such a paint film is viewed at grazing incidence, and the film takes on a colour that is nearly complementary to the colour that is exhibited at normal angles of viewing. This effect is known as bronze, because of its resemblance to metallic reflection.

The combination of scattering and absorption that takes place in nonhomogeneous mediums has been treated mathematically by a number of investigators, but the mathematical theory cannot be

appropriately treated here. It must suffice to say that most opaque substances owe their colour to a combination of scattering and absorption within the body of the material.

**The Laws of Colour Mixture.**—The surface of a roofing material that looks brown when seen from a distance may be found, on closer examination, to consist of crushed green slate, red brick dust and some sort of black bonding material. The green light reflected by the slate particles and the red light reflected by the brick particles are mixed together in the eye when the viewing distance is so great that the individual particles cannot be resolved. This mixture of green light and red light is yellow; but the total quantity of yellow light is small, partly because of the low reflectances of the particles, and partly because the interstices between the particles, being black, make little contribution to the total amount of light reflected. Thus, the resulting colour is a dark yellow, and the common name for all dark yellows is brown.

Colours produced in the above manner are said to be additive mixtures because the components add their individual contributions of light to the resultant mixture. The essential characteristics of this type of mixture are even more apparent when the mixture is produced by means of a Maxwell disk like that shown in fig. 8. In this illustration, the components are a red, a green and a black in equal proportions; and the spinning disk is brown for the reasons outlined in the preceding paragraph.

FIG. 8.—MAXWELL COLOUR DISK

In additive mixtures involving the addition of two or more beams of coloured light, as in theatrical lighting, the spectral energy of the mixture at each wave length is the sum of the spectral energies of the components. It follows that each of the three tristimulus values of the mixture is likewise the sum of the corresponding tristimulus values of the components. When the mixture is made by means of an unresolved pattern or by spinning the colours on a Maxwell disk, the components are not independent of one another, since increasing the relative area allotted to one component reduces the area occupied by the others. In this case, the tristimulus values of each component are multiplied by its fractional area before performing the addition. As an example of the foregoing, the tristimulus values of a typical sample of the artist's pigment chrome yellow are  $X=68.4$ ,  $Y=63.0$  and  $Z=9.6$ . When one-third of a Maxwell disk is of this colour and the remaining two-thirds has the colour of cobalt blue, whose tristimulus values are  $X=18.3$ ,  $Y=16.8$  and  $Z=67.2$ , the tristimulus values of the additive mixture produced by spinning the disk are  $X=34.8$ ,  $Y=32.2$  and  $Z=48.0$ . The trichromatic coefficients of this mixture are  $x=0.303$  and  $y=0.280$ ; and, by reference to a large-scale chromaticity diagram, it is found that this mixture is a purple whose dominant wave length is 558, and whose purity is 13.7%.

Those whose knowledge of colour is limited to empirical observations concerning the behaviour of dyes and pigments in the ordinary type of mixture would expect a combination of yellow and blue to produce green rather than purple. That is, if a yellow pigment and a blue pigment are intimately mixed in a transparent vehicle, such as linseed oil, a green paint is the usual result. The reason is simple when the optical mechanism involved in the production of body colour is kept in mind, because it is easily seen that the light incident upon the paint film must, on the average, pass through many particles of both pigments before emerging again as reflected light. A characteristic feature of strong yellow substances is their ability to absorb blue light and violet light, while transmitting all other visible radiations quite freely. Typical blue substances, on the other hand, absorb yellow light, orange light and red light, while transmitting blue light and violet light. As a consequence, the only spectral component that is not strongly absorbed by either pigment is green. If the paint film has the requisite scattering properties, this green light ultimately finds its way

back to the surface through which it entered the paint film. Thus, the subtractive mixture of yellow and blue produces green because the other components of white light are so strongly absorbed within the body of the material.

The colour that results from a subtractive mixture is readily calculated in the case of two transparent substances, such as two coloured glasses, arranged in tandem so that the light must pass through both before reaching the observer. Neglecting the small amount of light reflected at the surfaces, the spectral transmittance of the pair at any wave length is the product of the spectral transmittances of the components at the corresponding wave length. The tristimulus values of the combination can be found by applying the standard procedure to the spectral transmittance data thus calculated. Unlike the case of additive mixtures, the tristimulus values of a subtractive mixture ordinarily cannot be calculated from the tristimulus values of its components. In other words, the visual colour of the components is not a reliable guide to the colour of their mixture. Instead, one must know the spectral absorption characteristics of the components—information that only a spectrophotometer can provide.

The laws of subtractive mixture are vastly more complex in the case of a paint film or a dyed textile fabric. Probably the most complex case of all is that of a plastic material that may contain particles of pigment as well as molecules of dye. Although the mathematical theory concerning the behaviour of light in the presence of absorption and scattering enables the change in colour of such a material with thickness to be calculated for both the reflected light and the transmitted light, it does not enable the colour of such a material to be readily calculated from the measured characteristics of its components. Nor can the optical absorption characteristics of even a single substance be readily calculated from its molecular or atomic structure.

In the field of photography, the entire colour gamut of a colour reproduction is customarily achieved by mixing three primaries in various proportions. The original three-colour process, invented by Maxwell in 1855, reproduced the colours of the subject by appropriate additive mixtures of red light, green light and blue light. Although Maxwell's choice of primaries seems to have been based on a slightly erroneous deduction from Thomas Young's theory of colour vision (*see* VISION), the fact remains that the use of a deep red, a strong green and a deep blue provides the greatest gamut of possible colours in the reproduction.

The many ingenious methods of colour photography employing additive mixtures have been largely superseded by the more convenient subtractive methods. The starting point of all subtractive methods is a white projection screen or a sheet of white paper, either of which can be regarded as reflecting a mixture of red light, green light and blue light. In a projection system, three registered dye images, arranged in tandem, are inserted in the projector. In the case of colour prints, similarly registered images are superimposed on the surface of the white paper. In the latter case, the incident light passes through the three images, is reflected by the white paper and passes again through the three images before reaching the observer.

In additive processes, the colour gamut achievable with a set of primaries whose colours are known can be readily computed by application of the laws of additive mixture. This is true also of some of the subtractive processes employed in the graphic arts because the fact that the images are composed of dots makes these processes the equivalent of an eight-colour additive process. In general, however, the calculation of the colour gamut of subtractive processes is so laborious that it is simpler to determine it experimentally. Of course, certain characteristics of the most desirable set of subtractive primaries are obvious. If black is to appear in the reproduction, every component of the visible spectrum must be strongly absorbed by at least one of the primaries. Also, the fact that additive processes have the greatest gamut when the primaries are red, green and blue makes it reasonable to expect that the greatest gamut in subtractive processes will be achieved when the primaries are, respectively, red-absorbing, green-absorbing and blue-absorbing. Of course, the colour of an image that absorbs red light while transmitting all other radiations is blue-green, often

called cyan. An image that absorbs only green light transmits both blue light and red light, and its colour is magenta. The blue-absorbing image transmits only green light and red light, and its colour is yellow.

The same principles apply in the mixing of pigments in a paint. If three pigments are to be capable of producing the greatest possible colour gamut, they must have the same optical absorption characteristics as the dyes of a three-colour subtractive process in photography. In 1933 Herbert E. Ives made a systematic study of the spectral absorption characteristics of all the readily available pigments, and he concluded that an artist's palette containing only three properly chosen colours is entirely adequate under most circumstances. The practical advantages of such a simplified palette result in part from the fact that the use of certain pigments of questionable permanence can be avoided and in part from the simplification of the laws governing the colours that mixtures of these pigments will produce.

No concepts in the field of colour have traditionally been more confused than those just discussed. This confusion can be traced to two prevalent misnomers: the subtractive primary cyan, that is properly a blue-green, is commonly called blue; and the subtractive primary magenta is commonly called red. In these terms, the subtractive primaries become red, yellow and blue; and those whose experience is confined for the most part to subtractive mixtures have good cause to wonder why the physicist insists on regarding red, green and blue as the primary colours. The confusion is at once resolved when it is realized that red, green and blue are selected as additive primaries because they provide the greatest colour gamut in mixtures. For the same reason, the subtractive primaries are, respectively, red-absorbing (cyan), green-absorbing (magenta) and blue-absorbing (yellow).

**The Use of Colour.**—Colour plays so important a role in every department of modern life, and its every application is surrounded by so many special circumstances, that only a few general comments can be made concerning the features that are common to many of its applications. Ordinarily, the first problem in the use of colour is to decide what colour or colours to use. Science has been of little aid in this connection, not because its methods are necessarily inadequate, but rather because the tools of colorimetry had first to be developed. In a negative sense, science can supply the information that no harmonic combinations, comparable to chords in music, seem likely to be discovered. Light and sound are different forms of wave motion; the eye has only rudimentary powers of analysis by comparison with those of the ear; and, at best, the entire visible spectrum comprises less than one octave. Nor is there a physical or physiological basis for believing that some colours per se are always desirable and others undesirable. The spectral array of colours exhibited by a rainbow is a glorious sight; and no one seems ever to have suggested that it would be improved by the omission of one or more of the components.

Of course, a civilization as old as ours has developed taste in colour, as it has in music. Through the centuries, many musical forms have been created, and each has come to be considered appropriate on some occasions and inappropriate on others. A similar sense of fitness has been acquired concerning the use of colour, but there is a significant difference between the two arts. One can be specific when discussing the musical form or the particular composition that would be appropriate for a given occasion because a standard method of musical notation was developed early; whereas the development of standard methods of colour notation was long delayed. The factors that determine the appropriateness of a colour scheme are numerous, and the influence of each is best determined by statistical analysis, now that colour can be measured. Such analyses fail to show truly universal principles underlying good taste in colour.

For the manufacturer of a coloured product, the selection of the colour is only the first step. He must then formulate the paint, make the appropriate mixture of dyes or do whatever is required to match the colour selected. For example, the original design for a soap wrapper may be a water-colour sketch prepared by an artist. The printer who prints the soap wrapper must duplicate the colour, but the number of commercially available pigments is

so great that the artist's sketch can be matched visually by a variety of ink formulations. Hence, at the outset, the printer will normally investigate many different formulations from the standpoint of cost, permanence to light, resistance to alkali, etc. This second step in the use of colour is common to many industries.

In the mass-production industries, the third step is the establishment of the maximum colour tolerances that are to be allowed. The size of a just perceptible colour difference has been systematically investigated on a number of occasions, but holding the colour of the product within such fine limits is seldom justified from an economic standpoint. Nor is it safe to assume, in applying the results of these investigations, that the size of the tolerance should represent an equal number of just perceptible steps in every direction throughout the colour space. For example, the natural colour of butter varies from month to month with its carotene content, and it is standard practice in the dairy industry to add a harmless yellow dye to compensate for the carotene deficiency. If the proper dye is used, the allowable colour tolerance is large because the public is aware of the fact that the natural colour of butter can vary from nearly white to a strong yellow. In a three-dimensional colour space, the locus of these natural variations is a line; and the length of this line corresponds to many just perceptible steps of colour difference. The same number of just perceptible steps in another direction might not be tolerated at all. Indeed, butter would probably be quite unpalatable if it were green.

**COLOUR BLINDNESS:** see VISION: *Seeing Colour: Deficiencies of Colour Vision*.

**COLOURS, MILITARY:** see FLAG: *Other Flags: Military Colours*.

**COLT, SAMUEL** (1814–1862), U.S. inventor of the Colt revolver, was born July 19, 1814, at Hartford, Conn. He ran away to sea at 16, sailing from Boston, Mass., Aug. 2, 1830, for India. During this voyage he whittled a wooden model of a revolver and upon his return to the U.S. had several metal models made between 1831 and 1835. Having perfected his invention—a single-barreled pistol or rifle having a many-chambered rotating breech which was turned, locked and unlocked by cocking—he took out English and European patents in 1835 and a U.S. patent in 1836. On March 5, 1836, the Patent Arms Manufacturing Co., of Paterson, N.J., was formed to manufacture and sell the new weapons, but lack of general acceptance caused the company to fail in 1842.

Colt then turned to the invention of electrically discharged submarine mines. He also conducted a telegraph business, which utilized the first cable ever laid under water. At the outbreak of the Mexican War, 1846–48, Colt received a government order for 1,000 revolving pistols. These were made at the factory of Eli Whitney at Whitneyville, Conn. Colt established his own plant at Hartford in the latter part of 1847, and thereafter the business grew rapidly. He moved twice until, in 1855, he set up the largest private armory in the world on the site of the present Colt plant in Hartford.

Colt developed beyond any maker before him the manufacture of interchangeable parts and the production line. He also had advanced ideas concerning working conditions and employee welfare. His invention netted him one of the outstanding fortunes of the period. He died at Hartford, Jan. 10, 1862. (C. T. H.; X.)

**COLUMBA** (COLUM or COLUMCILLE), **SAINT** (c. 521–597), Irish missionary and abbot who founded the monastery of Iona, was born in County Donegal. His father, Feidlimid, a member of a reigning family in Ireland, was closely allied to that of Dalriada (Argyll). To these connections as much as to his piety and ability Columba owed his immense influence. He studied under the distinguished Finnian of Moville (at the head of Strangford lough) and Finnian of Clonard, and c. 551 was ordained priest. During his residence in Ireland he founded a number of churches and the famous monasteries Daire Calgaich (Derry), on the banks of Lough Foyle, and Dair-magh (Durrow) in County Offaly.

About 563 Columba with 12 disciples established himself on the island of I or Iona, where he erected a church and a monastery and applied himself to the task of converting the Picts. By his preaching, his holy life and miracles he converted important parts of northern Scotland and established monasteries there, the monastery of Iona being regarded as the mother house and its abbots as the chief ecclesiastical rulers even of the bishops. Columba gave formal benediction and inauguration to Aidan (Aedan), the successor of Conall, as king of the Scots of Dalriada. He accompanied that prince to Ireland in 575 and took a leading part in a council held at Druim Cetta (modern Druim Ceata), which determined the position of the ruler of Dalriada with regard to the king of Ireland. The last years of Columba's life appear to have been spent mainly at Iona, where he was already revered as a saint. He died in the night of June 8–9, 597. His feast day is June 9.

Irish poems are ascribed to Columba, but they are manifestly of a later age. Three Latin hymns (edited by G. M. Dreves and C. Blume in *Analecta hymnica medii aevi*, vol. 51 [1908]) may be attributed to him with some degree of certainty.

See also IONA.

The principal source for the life of St. Columba is the *Life* written by St. Adamnan, ninth abbot of Iona, and edited by J. T. Fowler (1894). See J. F. Kenney, *The Sources for the Early History of Ireland*, vol. i (1929).

**COLUMBAN** (COLUMBANUS), **SAINT** (543–615), Irish missionary, abbot and writer, who initiated a revival of monastic and lay spirituality on the continent, was born in Leinster and educated in the monastery of Bangor, County Down. About 590

he left Ireland with 12 other monks and established himself in the Vosges at Annegray (Haute-Saône). He then built the abbey of Luxeuil (*q.v.*) nearby, for the congregation of which he drew up his rule. He was indicted before a synod of French bishops (603) for keeping Easter according to the Celtic usage, and a powerful conspiracy was organized against him at the court of Burgundy on the grounds of his bold rebukes to King Theuderich II. Being forcibly removed from his monastery in 610, he withdrew with St. Gall and other monks to Switzerland, where he preached to the Alamanni. On being compelled to leave, he went to Italy and founded the monastery of Bobbio, where he died on Nov. 21, 615. His writings, which include poems, letters and sermons, prove him a man of learning, acquainted with Latin and Greek classics. His feast day is Nov. 23.

St. Columban's works were edited by G. S. M. Walker, with an introduction and English translation (1957); they also may be found in J. P. Migne, *Patrologia Latina*, vol. 80, col. 201-326 (1850).

**BIBLIOGRAPHY.**—H. Concannon, *Life of St. Columban* (1915); J. F. Kenney, *The Sources for the Early History of Ireland*, vol. i, pp. 186-205 (1929); M. M. Dubois (ed.), *Mélanges Colombaniens* (1951).

**COLUMBANI, PLACIDO**, Italian architectural designer, who worked chiefly in England in the latter part of the 18th century. He belonged to the school of the Adams and Pergolesi, and like them frequently designed the enrichments of furniture. He was a prolific producer of chimney pieces, molded friezes and painted plaques for cabinets. English furniture designers of the end of the 18th century, and especially the Adams, Hepplewhite and Sheraton, owed much to his graceful, flowing and classical conceptions, although they are often inferior to those of Pergolesi.

**COLUMBARIUM**, a sepulchral building containing many small niches for cinerary urns, originally referred to a pigeon house or dovecot (it is still so used, particularly to refer to large, round, towerlike structures common in France, but "columbary" is the more prevalent term). The word acquired its later, commoner meaning by association of imagery.

Columbaria were common during the early Roman empire when cremation was normal pagan practice. They were usually erected and supervised by funeral societies to which most of the lower and middle classes in Rome belonged. Originating as variants of traditional Etruscan and republican Roman house tombs, they were ordinarily rectangular brick structures built around an open court, the walls of which contained niches for the urns. Some columbaria were very elaborate; their numerous inscriptions, stucco paintings and mosaics provide information about the otherwise almost totally forgotten life of the lower classes in antiquity. Perhaps the best examples of columbaria are those in the great heathen necropolis discovered in 1915 beneath the church of S. Sebastiano in Rome.

When in Hadrian's time (A.D. 117-138) inhumation replaced cremation in pagan practice, columbaria became obsolete. They did not reappear until the large-scale 20th-century revival of cremation, particularly in Germany and Scandinavia.

**COLUMBIA**, a city in central Missouri, U.S., midway between St. Louis and Kansas City, about 10 mi. N. of the Missouri river, is an important educational and cultural community; seat of Boone county. Settled in 1821 and incorporated in 1826, education early became Columbia's chief concern. It was selected in 1839 as site of the state university after Columbia and Boone county subscribed \$117,900. Christian college was organized in 1851 and Columbia Baptist Female college, predecessor of Stephens college, began in 1856. Growth of the city was handicapped by lack of water transportation or main line rail service. However, the highway system that developed in the 1920s placed Columbia at a major crossroads. Under council-manager government, established in 1949, Columbia rapidly expanded its municipally owned utilities, obtained airline service and sponsored public housing and urban-renewal projects. The city's manufactures include dairy products, furniture, women's clothing, brick

and tile. The state cancer hospital and the university's teaching and research hospital make Columbia a medical centre. Main and regional insurance offices and headquarters for professional, government and educational associations are also located there. Abundant cultural and recreational opportunities are afforded by its educational institutions. For comparative population figures see table in MISSOURI: *Population*. (J. C. C.)

**COLUMBIA**, a borough of Lancaster county in southeastern Pennsylvania, U.S., along the Susquehanna river, 75 mi. W. of Philadelphia. Laid out as a town in 1788 by Samuel Wright, it missed congressional selection in 1789 as the permanent U.S. capital by a 28-21 vote. Important in the state works system, 1834-57, as the terminal of the railway from Philadelphia, Columbia reshipped goods by canal to the Juniata river. Slaves knew it as a station on the underground railroad. Shad fishing, sawmills, rolling mills and railroading provided 19th-century employment. In the second half of the 20th century its manufactures included textile, metal and glass products. For comparative population figures see table in PENNSYLVANIA: *Population*. (V. BK.)

**COLUMBIA**, the capital and largest city of South Carolina U.S., and the seat of Richland county, situated in the centre of the state on the east bank of the Congaree river just below the confluence of the Broad and Saluda rivers. Pop. (1960) 97,433; standard metropolitan statistical area (Lexington and Richland counties), 260,828. (For comparative population figures, see table in SOUTH CAROLINA: *Population*.) Columbia's growth is largely due to its location; its highway, rail and airline facilities; its increasing importance as a location of federal and state government agencies; its continued development as an educational centre; the growth of industry; and the nearby location of Ft. Jackson, a permanent infantry training post.

Columbia's history dates from 1786 when the legislature ordered a town laid out on the site to replace Charleston as the state capital. Since the first meeting of the legislature in 1790 Columbia has been the chief focal point of South Carolina's political history. Conventions sitting there drew new constitutions in 1790, 1865 and 1895, nullified the federal tariff in 1832, and in 1860 (before adjourning to Charleston) made the decision to secede. The city was occupied by Federal troops and almost totally destroyed by fire in Feb. 1865. It suffered during the reconstruction period after the war and, as the state capital, witnessed at close range the political developments of later times.

Local government was by commissioners chosen by the legislature until incorporation as a village under elected officials in 1805; incorporation as a city came in 1854. The aldermanic form of government was changed to the commission type in 1910 and to council-manager in 1950.

Educational and cultural facilities include six institutions of higher learning, an active little theatre and numerous music and art organizations. The University of South Carolina was chartered in 1801 and opened in 1805 as South Carolina college. Other institutions are Columbia college for women (Methodist, 1854), Columbia Bible college (private, 1923), Lutheran Theological Southern seminary (moved to Columbia in 1911) and two colleges for Negroes: Benedict college (Baptist, 1870) and Allen university (Methodist, 1880).

Columbia is a city of broad avenues, beautiful homes and gardens and many imposing public buildings, notably a statehouse of native granite in Roman Corinthian style. A number of private homes and institutional buildings were designed by the distinguished architect Robert Mills. (C. E. CN.)

**COLUMBIA RIVER**, the largest river flowing into the Pacific ocean from North America, is one of the world's greatest sources of hydroelectric power. Its annual discharge of 180,000,000 ac.ft. (1 ac.ft. = 43,560 cu.ft.) is exceeded on the North American continent only by the Mississippi, Mackenzie and St. Lawrence. With its tributaries, the Columbia represents one-third of the potential hydro power of the United States.

The river drains 258,000 sq.mi., 85% in northwestern United States. Major tributaries are the Kootenay, Snake (*qq.v.*), Pend Oreille, Spokane, Okanogan, Yakima and Willamette. At The Dalles, farthest downstream point for which there is a long-term

record, average discharge is 195,500 cu.ft. per second (maximum, recorded June 6, 1894, was 1,240,000; minimum, 35,000 on Jan. 12, 1937). High flows occur in late spring and early summer with melting of snow on the mountainous watershed. Low flows occur in autumn and winter, causing power shortages.

The Columbia flows 1,214 mi. from its source in Columbia lake (elevation 2,700 ft.), in British Columbia near the crest of the Rockies, to the Pacific ocean at Astoria, Ore. For the first 190 mi. its course is northwesterly; then it flows southerly 270 mi. to the Canadian-U.S. border (elevation 1,290 ft.) where it enters northeastern Washington. It traverses east central Washington in a sweeping curve known as the Big Bend, its prehistoric course having been disarranged first by lava flows and later by ice sheets. Shortly below the mouth of the Snake, its largest tributary, the Columbia turns west and continues 300 mi. to the ocean as the boundary between Oregon and Washington, cutting through the Cascade and Coast ranges. From Portland, Ore., it flows northerly about 50 mi., then westerly another 50 mi. to the Pacific. Tides flow 140 mi. upriver. For most of its length, the river flows in deep valleys and canyons.

The Columbia provides the first deepwater harbour north of San Francisco. Channel improvement, inaugurated in 1877, has helped Portland (q.v.) become a major Pacific coast port. Aided by locks, ocean vessels may continue upstream to The Dalles. Channel depths of 35 ft. to Portland and 27 to The Dalles are maintained by the federal government.

Plans for a series of multiple-purpose dams on the Columbia river and the major tributaries of the river were advanced both by federal and by nonfederal agencies after the 1930s. The dams on the Columbia river either in operation or under construction in the second half of the 20th century are shown in the accompanying table in upstream order. Other dams for the purpose of converting the whole river into a series of pools from tidewater to the Canadian border were under consideration.

The Grand Coulee and Bonneville dams were put into operation prior to World War II, and several dams were built after the war. The four lower dams include large locks to permit the passage of river vessels, and several of the dams provide emergency flood-water storage. Grand Coulee, the largest and most complex of the dams, augments the low winter flows (when the power demand is greatest) for the entire system from its 9,402,000 ac.ft. of available storage (of which approximately 5,100,000 ac.ft. is active storage), and also pumps water to the Columbia Basin Irrigation project. Passage facilities for migrating fish are installed or planned at all but the upper two dams.

All the power plants are connected by high-voltage, federal transmission lines, backbone of the superpower grid in which all power utilities of the Pacific northwest participate. The federal government operates as a wholesaler of power, the only ultimate consumers it serves being federal agencies and heavy power-using industries (mainly aluminum plants). On June 1, 1958, this superpower grid connected 8,565,000 kw. of installed capacity. The Federal Power commission expected the regional power demand to be double this amount by 1975.

Many controversies have marked development of the Columbia, especially concerning the division of responsibility between public and private agencies; the effect on fish; proposals for a Columbia Valley authority; the assignment of some joint costs to navigation and flood control, for which no direct repayment is made to the federal treasury; the proper rate of interest to be charged on the federal power investment; and arrangements for sharing power

revenues and costs with Canada for any upstream storage reservoirs built in British Columbia. In 1961 the Columbia River treaty was signed by the United States and Canada providing for co-operative development of the river with storage projects upstream in British Columbia and power generation projects downstream in Washington and the sharing of flood control costs and benefits and of increased power production resulting from the program.

The Boston trader Capt. Robert Gray discovered the Columbia in 1792, naming it for his ship. The Lewis and Clark expedition (q.v.) wintered at its mouth in 1805-06, and David Thompson explored the upper basin for the North West company in 1807-11. Early posts were established at Astoria (1811) and Vancouver (1825).

**COLUMBIA UNIVERSITY**, one of the oldest of the major universities in the United States, has its main campus in a section of New York city known as Morningside Heights.

In 1754 a group of civic-minded citizens, desiring to establish a college in the province of New York, obtained a royal charter that created "a Body Corporate to erect and maintain a College to be known as King's College for the Instruction and Education of Youth in the Learned Languages and Liberal Arts and Sciences." The charter was free from narrow sectarianism, providing that the governors should not "exclude any person of any religious denomination whatever from equal liberty and advantage of education or from any of the degrees, liberties, privileges, benefits or immunities of the said college on account of his particular tenets in matters of religion." The first president of King's college, Samuel Johnson (1696-1772), carried out this purpose, which has been a basic principle of the institution.

The first classes were held in the vestry room of Trinity church. Enrollment was limited to men. In 1756 the college moved to its first permanent home erected on land granted by Trinity church. This site, now known as Park place, two blocks west of the city hall, continued to serve the educational needs of the growing city until 1776 when the Revolution forced the college to close, its building being used to house troops.

In 1784 King's college was reopened and renamed Columbia college. The college moved in 1857 to a site at 49th street and Madison avenue. It was during this period that Columbia acquired the land on which much of Rockefeller centre stands. Continued growth in its educational organization led to a third move to the present site in 1897.

Columbia university embraces four separate corporate units within its educational framework, joined through the direction of the educational interests of the university council. This body, an academic senate, is composed of the president, the major administrative officers and deans and elected representatives from the faculty of each school.

Affiliated units are the College of Pharmacy (1829) located on W. 68th street, part of the university since 1904; Teachers college, founded in 1889 as the New York College for the Training of Teachers and a part of the university since 1898; and Barnard college, the undergraduate liberal arts school for women, founded in 1889 and a part of the university since 1900. Reciprocal relations also have existed since 1891 between the university and Union Theological seminary. The divisions that form a part of the university corporate unit and their dates of establishment within the university are Columbia college, the liberal arts college for men (1754); the college of physicians and surgeons (1767), at 168th street where, with the Presbyterian hospital and allied institutions, it forms the nucleus of a great medical centre; the school of law (1858); the school of engineering, organized as the school of mines in 1864; the school of architecture (1881); the graduate faculties of political science (1880), philosophy (1890)

BY COURTESY OF COLUMBIA UNIVERSITY

LOW MEMORIAL LIBRARY (1897). NOW CENTRE OF ADMINISTRATION AT COLUMBIA UNIVERSITY, MORNINGSIDE HEIGHTS, NEW YORK CITY

and pure science (1892), for advanced studies in those fields; the school of journalism (1912); the graduate school of business (1916); the school of dental and oral surgery (1916); the school of public health (1921); the school of library service (1926); the New York School of Social Work (1940); the school of international affairs (1946); the school of general studies (1947), the successor to university extension (1920); and the program in the arts, the interim division for the schools of dramatic arts and painting and sculpture (1948). Except for Columbia college and Barnard, all these schools are coeducational.

Barnard college, which occupies four acres of land adjacent to Columbia university, has a president, faculty and trustees of its own, and is responsible for its financial endowment. Members on the university staff also give instruction. The music, classics, mathematics, physics and religion departments are joint departments with Columbia, and some undergraduate classes are held with Columbia college. The college offers a four-year liberal arts curriculum to women. Upon graduation, a Barnard student receives the degree of bachelor of arts conferred by Columbia. In the 1960s enrollment was about 1,400 students, about one-third of them residents, from nearly every state of the U.S. and from as many as 30 other countries. In 1952 Millicent Carey McIntosh became president of Barnard.

A series of institutes offer specialized study and research. The American Press institute provides a series of seminars annually for every level of personnel in the newspaper industry. There are area institutes giving specific training in Russian, east Asian, near and middle eastern, east central European and Israeli and Jewish studies. The American assembly, established in 1950 at Harri-man, N.Y., serves as a forum for discussion of broad policies of national and international importance.

The university enjoys reciprocal agreements with such institutions as the American Museum of Natural History, the New York Botanical garden, the New York Zoological society, the Metropolitan Museum of Art and the Museum of Modern Art. Besides its Lamont Geophysical laboratory at Alpine, N.Y., and its cyclotron at Nevis estate, Irvington, N.Y., the university has associated organizations and facilities at the Marine Biological laboratory, Woods Hole, Mass.; the Long Island Biological laboratory, Cold Spring Harbor, N.Y.; the Brookhaven National laboratory, Upton, N.Y.; and the Yale-Columbia Astronomical observatory in Adelaide, Western Australia.

The numerous university publications include works embodying the results of original research published by Columbia University Press; "Studies" published in the form of a series by each of several departments; various periodicals, such as the *Romanic Review*, the *Germanic Review*, the *Political Science Quarterly*, etc., edited by members of the faculty; the *Columbia Forum*, a quarterly journal; and several papers or periodicals published by the students, among which are the *Columbia Spectator* (a daily paper), the *Columbia Law Review* and the *Columbia Jester*.

The campus at Morningside Heights includes, besides the several departmental buildings and laboratories, two library buildings. Butler library is the centre of an extensive system with divisions in a number of other university buildings; Low Memorial library is primarily used for administrative offices, but has three special libraries. Other buildings are University hall (with gymnasium), Earl hall (for interfaith activities), St. Paul's chapel, the president's house, the Faculty club and the Citizenship centre. The total number of university buildings on the Morningside campus is about 70.

Presidents in the 20th century have been Seth Low (1890-1901), Nicholas Murray Butler (1902-45), Dwight D. Eisenhower (1948-53) and Grayson Kirk (1953- ). Frank D. Fackenthal was acting president, 1945-48.

See the several volumes of *The Bicentennial History of Columbia University* (1954).

(Rd. H.)

**COLUMBINE**, any plant of the genus *Aquilegia* of the crow-foot family (Ranunculaceae; *q.v.*). They bear slender, delicate, long-stalked, deeply divided leaves with blunt segments and loose panicles of handsome, drooping, blue, red, white or yellow flowers, which are characterized by having all the five petals spurred. Columbines grow in woods and thickets, and often in alpine meadows. Some horticultural varieties are well known in cultivation. There are about 70 species of columbine, natives of north temperate regions, together with numerous varietal forms and crosses developed by cultivation.

The 20 or more species found in North America, chiefly in the Rocky Mountain region, rank among the most beautiful wild flowers of the continent, several of which, including the following,

are widely cultivated. The eastern columbine (*A. canadensis*), called also honeysuckle and rock bells, found in dry woods from Nova Scotia to Saskatchewan and southward to Florida and Texas, with nodding scarlet and yellow flowers, an inch or more across, is a favourite spring wild flower. The Rocky Mountain columbine (*A. coerulea*), with handsome, erect, blue and white flowers, two inches or more across, and spurs two inches long, is the state flower of Colorado. The golden columbine (*A. chrysantha*), found from western Texas to Arizona, grows three feet to four feet high, with clear yellow flowers, sometimes three inches across, and very slender spurs about three inches long. The Sitka columbine (*A. formosa*), which ranges from Utah and northern California to Montana and Alaska, has nodding red and yellow flowers, about two inches across, with short, thick spurs. The common columbine of California is a form of this latter species, with pendulous scarlet flowers and short spurs. Many horticultural forms have been derived from hybridization and selection. The showy Eurasian *A. vulgaris* has been especially prolific in the production of new varieties. White, lilac, mauve, double-flowered and purple forms are cultivated and these have been crossed with several American species, notably *A. coerulea*. Columbines are of easy culture in most ordinary garden soils, except the rare alpine species, which demand a rock garden. All the showy hybrids can be grown in partial shade or full sun.

(N. Tr.)

**COLUMBITE (TANTALITE)**, a mineral series consisting of columbate (niobate) and tantalate of iron and manganese, which provide important ores of tantalum (*q.v.*) and columbium (see Niobium). It was in this mineral that Charles Hatchett discovered, in 1801, the element columbium (niobium) which he named after the country (Columbia, or America) whence came the specimens in the British museum collection which he examined.

The general formula is (Fe, Mn) (Nb, Ta)<sub>2</sub>O<sub>6</sub>, in which both the iron and columbium are replaced by varying amounts of man-

J. HORACE MCFARLAND COMPANY

BLOOMING CRIMSON STAR COLUMBINE (*A. VULGARIS OLYMPICA*)

ganese and tantalum respectively. Columbite ( $\text{FeNb}_2\text{O}_6$ ) crystallizes in the orthorhombic system and the black, opaque crystals are often very brilliant with a submetallic lustre. Hardness is 6; specific gravity, 5.3. With an increasing amount of tantalum the specific gravity increases up to 7.3, and members at this end of the series have been given the name of tantalite ( $\text{FeTa}_2\text{O}_6$ ). These minerals occur as crystals and compact masses in granite and pegmatite and in placer deposits. (CL. F.)

**COLUMBIUM:** see NIOBIUM.

**COLUMBUS, CHRISTOPHER** (Sp. CRISTÓBAL COLÓN) (1451–1506), discoverer of the new world, was the son of Domenico Colombo, a weaver living first at Genoa and later at Savona, and of Suzanna Fontanarossa. The exact date of his birth is not known. The evidence concerning the early life of Columbus is sparse and admits of many interpretations. One view is that Christopher at first followed his father's business and resided at Genoa and Savona, but Columbus must be believed when he says that he began to navigate at 14. In any event, he was a corsair in the service of René d'Anjou in 1472–73; he was on the Greek island of Chios in 1473–74; and he fought in a battle off Cape St. Vincent, under his namesake and probable relative Guillaume de Casenove-Coullon, on Aug. 13, 1476, when his ship took fire and he swam to the Portuguese coast with the help of an oar. The fact that in this battle he fought on the Portuguese side, against Genoa, shows him to have been no Genoese patriot. There is no explicit statement by him declaring himself a Genoese. He never went back to Genoa. He never wrote in any form of Italian, not even to his brothers, or to Genoese persons and institutions, but always in Spanish. He wrote in Spanish, even his own private notes certainly three years before he came to Spain, and the mistakes in his Latin are definitely Hispanisms. Columbus signed himself successively Colombo, Colomo, Colom and Colón. The latter was the form he himself came to prefer and wished to be used. He never took the traditional form "Columbus," not even when writing Latin. His brothers also, in Spain and the Indies, called themselves Colón and hispanized their Christian names (Bartholomeo becoming Bartolomé and Giacomo, Diego). One explanation of all these facts, as well as certain features of his character, is that Columbus came from a Spanish-Jewish family settled in Genoa.

**Columbus' Plan.**—It is a fact that Columbus discovered America by prophecy rather than by astronomy. "In the carrying out of this enterprise of the Indies," he wrote to King Ferdinand and Queen Isabella in 1502, "neither reason nor mathematics nor maps were any use to me: fully accomplished were the words of Isaiah"—referring to a more or less apposite passage in Isaiah xi, 10–12—and, in fact, any writing became prophetic in his eyes when it could be interpreted as a forecast of his discovery. Nor is it any wonder that he felt sure of having been divinely selected for a mission, an assurance to which he often gives vent in his writings and which is the source of both his pride and his humility, because his was a life rich in dramatic scenes. His very arrival in Portugal, miraculously saved from the wreck of his ship, his landing so close to the rock of Sagres where Prince Henry the Navigator had established his academy of seaman-ship, do seem to justify his sense of having been chosen.

Portugal was then the westernmost end of the known world and Lisbon the natural meeting place of mariners bent on discovery. From there the Portuguese had discovered Madeira, turned the forbidding Cape Bojador and reached the Tropic of Cancer, and it was in Lisbon that these and future exploits were talked about, prepared, financed and manned. The city was already a busy centre for the arts and sciences, particularly cosmography and astronomy. It was probably there that Christopher came

across his younger brother Bartolomé, who had also left home for the sea and was working as a cartographer.

The idea of reaching the east by sailing westward seems first to have been mooted by the Florentine cosmographer Paolo Toscanelli. A concession that may be interpreted as contemplating such a quest was granted by the king of Portugal to one Fernão Telles on Nov. 20, 1475. Soon after landing in Portugal, Columbus sailed to Iceland, and during this voyage seems already to have been thinking of his voyage to "Cathay" through the west. In 1478 he married Filipa Moniz Perestrelo; by this marriage, Columbus had a son, Diego, born in 1479 or 1480. He then settled for a time on the island of Porto Santo, Madeira Islands, of which his brother-in-law had inherited the captaincy. From this base he acquired a considerable sailing experience of the South Atlantic and a number of hints (big canes, pine tree trunks, pieces of wrought wood) as to probable lands beyond the western horizon.

Back in Lisbon, Columbus read assiduously in Cardinal Pierre d'Ailly's *Image of the World* and Marco Polo's account of the east. But though he studied Ptolemy and certainly knew Toscanelli's opinion, the system of ideas he elaborated owed most to "the prophet" Esdras. (See *ESDRAS, FIRST BOOK OF*.) These ideas were: (1) the earth is round; (2) the distance by land between the edge of the west (Spain) and the edge of the east ("India," i.e., Asia) is very long; (3) the distance by sea between Spain and "India" is therefore very short; (4) the length of a degree is 56½ mi. These "miles" were not Arabic (1,975.5 m.) which would have made the figure remarkably accurate, but Italian (1,477.5 m.) which made his equator about one-quarter too small. Columbus calculated that the land distance between Spain and "India" was 282°; he was therefore left with only 78° for the sea distance, which he further reduced by his method of reckoning the degree. The outcome of all these errors was that "India" would be about 3,900 mi. from the Canaries; i.e., more or less where America happens to be. This tallied tolerably well with Esdras who asserts that the earth is six parts dry land and one part sea.

**Quest for a Patron.**—This system set Columbus' imagination afire with the untold avenues for discovery that the western way opened up. It is unlikely that he was ever clear as to the exact nature of such avenues: new lands? new ways to sail to the old lands? Although vague about his plan, however, Columbus was clear about what he wanted in exchange: honour and wealth, definitely in that order. The proposal was finally put to the king of Portugal, who rejected it (1484). Columbus then went to Spain. He applied first for help to the powerful duke de Medina-Sidonia, who was not interested, then to the conde (late duque) de Medinaceli, who housed and sheltered Columbus from 1484 to 1486; but though he conceived the idea of letting him have some caravels, he decided in the end that the enterprise was too big for even as big a subject as he was, and sent the would-be discoverer to King Ferdinand and Queen Isabella. The queen handed the matter over to Alonso de Quintanilla, her chief accountant, and eventually Columbus met Ferdinand and Isabella in Córdoba in the spring of 1486.

The monarchs then decided to set up a special commission of "learned men and mariners" to study Columbus' proposals. This commission, under the chairmanship of the queen's confessor, Hernando de Talavera, then bishop of Ávila, made him wait four years. This was not, as is often asserted, because the commission was either incompetent or backward in its views, for it was not, but because Columbus was vague and secretive as well as incoherent. For four years he went from city to city, following the court. In Salamanca he became acquainted with Diego de Deza, a professor at the university there, who in 1486 became the tutor of Don Juan, the heir to the throne. Thanks no doubt to Deza, who throughout his life was to be his main stand-by, Columbus received several sums of money from the royal treasury in 1487, and on May 12, 1489, he was granted the privilege of being lodged and fed at public expense on his travels to court. During this period he became entangled with Beatriz Enriquez, who was to be the mother of his son Fernando (b. Aug. 15, 1488).

In 1490 the Talavera commission reported unfavourably; and though the king and queen did not abandon him, Columbus may

COLUMBUS, PROBABLE PORTRAIT BY SEBASTIANO DEL PIOMBO

have felt that his Spanish quest was at an end. He went to La Rábida, near Huelva, where he met two men who were to restore his faith: the friar-astronomer, Antonio de Marchena, and a pilot and shipowner from Palos, Martín Alonso Pinzón. Pinzón told him that a year earlier, in Rome, he had been informed by a papal cosmographer "of those lands which were still undiscovered." Columbus asked him to become his partner, and Pinzón accepted. The evidence available suggests that the two Rábida friars, Juan Pérez and Marchena, succeeded in having Columbus recalled to the court—not to discuss his plan this time but to name the price he set on it. The price was exorbitant. He was to be knighted, appointed grand admiral and viceroy (these titles to remain in his family forever), and he was to receive 10% of the transactions within his admiralty. The king and queen were stunned by his audacity. He held his ground so firmly that no compromise was possible, and he was dismissed. He left Santa Fé (the city camp built to besiege Granada) early in Jan. 1492, possibly for France and England, but friends at court persuaded the king and queen to recall him, and all was done as he wished.

**First Voyage.**—Thanks to his own and to Pinzón's drive, obstacles and inertia were conquered, and soon Columbus beheld at quay, ready to sail, his three vessels, the decked ship "Marigalante" (officially renamed "Santa Maria"), and two caravels, "Pinta" and "Niña." The first was about 117 ft. long, the other two about 50; the first two had castles fore and aft, the "Niña," only aft. They were armed with 4-in. *bombardas* for heavy granite balls and *espingardas* for smaller lead projectiles. As Columbus was uncertain whether he was to come across new savages or old civilizations, he loaded his ships with cheap merchandise to relieve aborigines of their gold, but also took on board one Luis de Torres—"who had been a Jew and knew Hebrew and Chaldean and a little Arabic"—in case he met the "grand khan." More than 1,000,000 maravedis had been supplied by the crown, though the story that the queen pawned her jewels to provide the money is quite untrue. The sum of 500,000 maravedis was supplied by Columbus himself (advanced by Pinzón). The "Santa Maria" sailed under Columbus; the "Pinta" under Martín Alonso Pinzón with his brother Francisco Martín Pinzón as his pilot; and the "Niña" under Vicente Yáñez Pinzón, another brother, later to prove one of the finest sailors of the era. (See also PINZÓN.)

On Aug. 3, 1492, half an hour before sunrise, the small fleet sailed out of Palos. On Aug. 12 it reached the Canary Islands, where it stayed until Sept. 6, when at last it sailed resolutely westward. Once the three ships finally lost sight of land (Sept. 9) the greatness of Columbus began to reveal itself, for it was at this moment that he conquered by faith and will power the resistance of the unbelieving and faint-hearted. He showed a typical mixture of strategic resolution and tactical caution, for he quickly handed out an "instruction" to his crews that after 700 leagues they were not to navigate at night because land would certainly be near. On Sept. 13 he observed the earth's magnetic variation, a memorable discovery, but one which he might have wished to have made on a less hazardous occasion. A whole month passed in alternation of good and bad weather, good and bad mood. "There will be no wind to come back," the unbelievers sighed; and a strong contrary wind came to the rescue of their leader. On Sept. 25, Columbus himself was infected by doubt and sought the help of Pinzón, who that very evening "saw" land. Columbus altered course to southwest in search of it but it vanished. Disbelief led to a conspiracy that might have degenerated into a disastrous mutiny but for the spirited intervention of Pinzón. On Oct. 6 Pinzón suggested altering course again to the southwest; but Columbus was too proud to listen. The next day the "Niña" again "saw" land, but it was another illusion. Flights of birds all southwestward, however, made Columbus swallow his pride and follow Pinzón's advice (Oct. 7). "All the night they heard birds passing," and carved sticks and reeds, picked up, gave them comfort and hope. Two hours after midnight (Oct. 12) a sailor named Rodrigo de Triana or Juan Rodríguez Bermejo saw land from the prow of the "Pinta."

**The New World Discovered.**—At dawn, a land of virginal beauty and fresh colour revealed itself to the delighted Spaniards. With his two captains and the fleet officials, Columbus went ashore

carrying the royal banner. He planted it on the shore and took possession of the land in the name of Ferdinand and Isabella. This land—of which he had, of course, no idea—was Guanahani, one of the Bahama islands, which the Spaniards renamed San Salvador. But everything he saw persuaded Columbus that he was among "the islands which are set down in the maps at the end of the Orient." So, although he saw signs of gold on the noses of the natives, he left in a hurry to see "whether I can come across the Island of Cipango" (i.e., Japan).

For a fortnight he wandered among lovely islands to which he gave Spanish names, hoping "the Lord would show him where gold is 'born,'" yet already alive to the possibilities of what would now be called economic development. He even thought of slavery. In his mind seemed to combine and struggle the two different strains that, curiously enough, appear also in his name: Christ-bearer; Colonizer. He raised crosses everywhere, but he kept an eye on the material value of things even to the extent of seeing men as goods for sale. His honeymoon with the islanders may have ended on the day when he took away by force seven of them from Guanahani. They began there and then to think of the Spaniards as only a shade less tyrannical than the *caniba* or "cannibals," who from islands further south came to take them away and eat them. Columbus was convinced that these *caniba* were the subjects of the great can or khan. This "fact" persuaded him that a big island so often mentioned by the islanders as Cuba was Cipango itself. This became the more certain in his mind when he found that in Cuba, when he asked where gold "was born," he was told: "In Cubanacan" (*nacan* meaning the centre of the island). He sent Luis de Torres to interview the khan, but Torres found neither the khan nor the source of gold. He did, however, discover a greater source of wealth—tobacco. The fleet sailed on. On Nov. 21 Pinzón and his "Pinta" vanished before a strong east wind. Columbus was worried. Had Pinzón gone to discover the source of gold and to talk to the great khan before him? Or worse still, did he sail to Spain to steal from Columbus the glory of the discovery? In search of his vanished second-in-command he arrived in Haiti.

Columbus was so struck by the beauty of this island that he renamed it Española (Hispaniola), "the Spanish island" (he usually thought in terms of Spain as a whole, not of Castile or Aragon). He praised the natives for their intelligence, industry and handsomeness and thought that "they are good to be ordered and made to work, sow and do all that is necessary and to adopt our ways." At this point the "Santa Maria" ran aground in a strong wind and became a total loss. It happened exactly at midnight on Christmas day, 1492. The "Pinta" was not available, and Columbus lost no time persuading himself that God meant him to leave behind an establishment with all the men and stores he could not carry back in the "Niña." He named his establishment Villa de la Navidad, and chose 38 men to remain there under Diego de Arana, a relative of Beatriz Enríquez. Columbus left them food and stores for a year, including ammunition—so that the natives should obey "with love and fear"—and sailed for Spain (Jan. 4, 1493).

**Return to Spain.**—On Jan. 6 the "Pinta" turned up. Columbus sailed back 40 mi. to seek a safe anchorage and he and Pinzón went through a stormy scene on board the "Niña." Pinzón's explanations were rejected, and his deeds disavowed. Columbus threatened to have him hanged from the castle door, which, Pinzón declared, "is what I deserve for having raised you to the honour in which you stand." The quarrel was patched up, although the two men remained estranged, and they sailed on. Columbus was worried about the men he had left behind—a decision of which Pinzón strongly disapproved—and by astrological considerations, let alone his own struggle between haste to return and report and curiosity to explore. At last, on Jan. 16, 1493, he sailed for Europe.

Columbus deliberately chose a more northerly course, roughly on the parallel of Cape St. Vincent, for his return voyage. The first weeks were happy and carefree, but in mid-February the ships met storms that threatened to drown the explorers. During the night of Feb. 14 both captains seem to have resigned themselves to let the wind do as it pleased; they signaled throughout the night but by dawn they had lost sight of each other. The storm raged on. Tormented by the thought that his discovery might remain un-

known, Columbus wrote out its story and entrusted it to a cask which he threw overboard. For four days he went without sleep, but on Monday, Feb. 18, he at last cast anchor at Santa Maria, the southernmost island of the Azores. He was so pleased that he let out in his journal that he had kept secret the distances covered daily in order to put sailors off the track of "his" Indies. On Feb. 24, 1493, he sailed for Spain. Worse storms assailed him, but at dawn on March 4, he recognized the rock of Sintra. He decided to enter the Tagus river. The Portuguese king received him on March 9 with full honours (though some of his courtiers, it appears, would gladly have killed him then and there) and suggested he go to Castile by land; but Columbus preferred his less unsafe element and on March 15 the "Niña" entered an enthusiastic Palos.

Pinzón arrived at Palos soon after on the same day, having sought refuge in Bayona, near Vigo, from which he wrote to the king and queen a letter loyal to Columbus. He died, exhausted, on March 20. Columbus also wrote to the king and queen who, upon receipt of his letter, wrote to him from Barcelona (March 30) asking him to come to court at once. They feared lest the king of Portugal should steal a march on them, and they wished to send a second expedition as soon as possible; they also obtained two papal bulls granting them the Indies discovered and to be discovered and apportioning the undiscovered parts of the west between the two Iberian powers by a line from pole to pole 100 leagues west of the Azores. The man who had started this keen rivalry between two powerful kingdoms marched in triumph from Seville to Barcelona, where at the end of April he was received by the king and queen in a scene of solemnity and splendour. The monarchs rose to greet him and offered him a stool. This was but the beginning of a flow of privileges and honours that staggered the court, including the right to display a castle and a lion (royal symbols) on his arms. Wealth and honour were his. He nevertheless insisted on being paid the prize of 10,000 maravedis promised to the first man of the crew to see land. The humble sailor who actually had first sighted land went over to Morocco in disappointment and became a renegade. This episode sheds some light on a side of Columbus' character that was to bring him much unhappiness.

**Second Voyage.**—Trouble began soon enough with the man the king and queen had put in charge of "Indian" affairs, Juan de Fonseca, afterward bishop of Burgos, but far more gifted as a soldier than as either an administrator or an ecclesiastic. Royal letters urged both Columbus and Fonseca to make haste; but the plan for the second expedition was ambitious: 17 vessels manned in all by between 1,000 and 1,500 persons. The material obstacles must therefore have been formidable enough, but much of the trouble came from personal differences between Columbus, Fonseca and two other officials, Juan de Soria and Francisco Pinelo. Soria was reluctant to treat an upstart like Columbus as a magnificent lord and had to be reprimanded for it by his royal masters; while Columbus himself was impatient of all supervision.

This second fleet was organized on the basis of a memorandum Columbus had prepared more as "Colonizer" than as "Christ-bearer." Populating and developing came to the fore, while Christianizing took what was left. But his ideas were sensible and he even suggested that gold-seeking was to be forbidden at certain periods of the year so that settlers could turn their attention to the land. The king and queen, however, added their own ideas: Christianization and welfare of the Indians; assertion of royal sovereignty over the new territories and the men who were sailing; greater stress on land cultivation than on gold. Several priests were sent, a doctor, a surgeon, peasants, hidalgos and Columbus' own brother Giacomo, who became known as Don Diego. The fleet sailed from Cadiz on Sept. 25, 1493.

After the usual stay in the Canary Islands to restock food and water and live animals for the new world, Columbus began his second crossing on Oct. 13. He chose a southwesterly course aiming at the mainland; this enabled him to benefit by the trade winds, and on Nov. 3 the expedition sighted land. They had the choice of Dominica and Marigalante (Marie Galante), and they anchored at the second. The next day they discovered Guadalupe (Guadeloupe) and later, Puerto Rico, all islands, though Columbus was looking for the mainland. He was also worrying about the men

he had left in Haiti. When he at last arrived there, he found that the Spaniards had been wiped out by the local chiefs. On hearing of the disaster, he remained cool, indeed cold, and he ordered a search for any gold the massacred men might have buried. Guacamari, the local "king," was unmasked by the doctor as a dissembler but the irresolute admiral allowed him to escape. Columbus sailed away in search of a better base on the island and kept moving for a month, at the end of which he chose a site and founded the first European city in the new world, Isabela.

**Quarrels and Exploration.**—From Isabela, Columbus sent to Spain his first messenger, Antonio de Torres, of the royal household, with a number of explanations, excuses and proposals, all of which were eventually approved except his scheme for a regular exchange of Spanish cattle for cannibal slaves. The news of the disaster at La Navidad, however, shook faith in him at court. Was the discovery worth the trouble and expense? His credit in the new world was also falling. The chief accountant of the fleet, Bernal de Pisa, wrote a report on Columbus for Juan de Soria, which he hid in a wooden buoy. The admiral ferreted it out, imprisoned the accountant and dealt no less severely with other "conspirators." Then he left for Cibao (March 12, 1494), a region of the island where gold was believed "to be born," leaving Isabela in charge of his inexperienced brother Diego. In Cibao he founded Santo Tomás, a settlement with a fortress, where he left 50 men under the command of a Catalan captain, Mosén Pedro Margarite.

On his return to Isabela (March 29) Columbus found the food putrid by the heat, the men hungry and angry. He tried to make them work to erect a mill (for he had wheat), and punished those who refused. Bernardo Buil, a Catalan friar who had come in charge of spiritual affairs, objected to his harsh ways (Columbus had several men hanged) and a conflict arose between the two powers. The friar struck the viceroy with interdicts and the viceroy countered by stopping the friar's rations. He sent a strong force to relieve Margarite and to explore the island.

Although the situation in Isabela and Santo Tomás was by no means good, Columbus sailed away again (April 24, 1494) taking with him 3 caravels of the 5 that remained after Torres' departure for Spain with 12; and he again left Isabela in the care of his brother, though now assisted by a council of men all of whom were better qualified than their chairman. Columbus was anxious to explore Cuba, which he sighted on April 29, but, induced by a converted Indian, christened Diego Colón, he veered southward and discovered Jamaica (May 13). All Jamaica's charms, however, could not lure him away from his westward urge, and within five days he sailed back toward Cuba determined to find out whether or not it was the mainland. His determination came suddenly to an end on June 13, when he was about 150 mi. west of the island. He returned to Isabela just because he made up his mind that Cuba was the mainland, which he forced everyone in his squadron to swear on oath under pain of having their tongues torn out should they recant. He sailed eastward, lingered at the Isle of Pines and sailed round the southern coast of Jamaica. He then fell ill and remained as dead for days. The fleet returned to Isabela (Sept. 29).

Columbus' brother Bartolomé had now arrived and was put in command with the title of *adelantado*, which, when known at court, was rightly considered an encroachment on royal authority. This step increased the discontent prevailing at Isabela. Margarite and Buil had left for Spain with many complaints against Columbus and his brothers. Torres returned with royal letters for the admiral congratulating him on his success and enjoining all and sundry to obey him. But, alleging that the natives were restive, he and Bartolomé left Isabela (March 24, 1495) to "pacify" them—in fact to take prisoners which might be justified as slaves. The natives were of course defeated. Columbus sent his trusted messenger Torres back to Spain with a report, together with his brother Diego and 500 prisoners. His human cargo arrived in Spain when Buil and Margarite had spread their unfavourable views on him. When Juan de Aguado, sent to Haiti by the king and queen to report on the situation, landed (Oct. 1495), he found the natives on the point of rebellion because Columbus had imposed a gold tax.

A duel of jurisdictions began between Aguado and Columbus which lasted five months and deeply humiliated the proud viceroy. He decided to leave, appointed Bartolomé as governor and Diego, who had returned from Europe, as his substitute, and sailed for Spain (March 10, 1496) on one of two caravels (the other had Aguado on board) which had been built in the island. Columbus lingered among his islands for weeks and finally began his crossing on April 20. On June 11, the first two American ships to arrive in Europe cast anchor at Cadiz.

**Third Voyage.**—Columbus chose to arrive in Franciscan habit as a protection against any further humiliations. He left at once for Seville and Burgos. His adversaries had the ear of the king and queen, but in July he received a royal letter of welcome. He prepared an efficient colonialist, but not very Christian, memorandum for the future organization of the Indies. He still possessed his fire and magnetism, however. He won over his adversaries, had all his privileges confirmed and some of the more material ones substantially increased, and was authorized to populate Haiti-Española with convicts. He declined a royal offer of an estate, in Española, 50 leagues east-west and 25 north-south with the title of duke or marquess, no doubt feeling that the estate to which he was entitled was no less than the whole new world.

Financial difficulties delayed the third expedition, which did not sail from Sanlúcar until May 30, 1498. It was composed of six ships conveying 200 men, excluding the sailors. On June 19 Columbus arrived in Gomera, where he rescued some Spanish ships from a French corsair, and then decided to send three of his ships directly to his brother and sail southwest with the other three. With one ship and two caravels he left Gomera on June 21, 1498, and called at the Cape Verde Islands. While anchored in one of them, Santiago, he was told of islands to the south. Southward he sailed in haste, until July 13. He then turned west. Had he kept his course, he would have discovered the Amazon within four days. By July 28 his course was parallel to the mainland he sought and he was only saved from a long frustration by a land crowned with three summits, which was sighted as he had ordered to alter course northward toward Dominica. He named the new land Trinidad. He sailed round the island, to the Gulf of Paria, saw the mainland, deemed it an island and left in a hurry, drawn by the call of his "mainland," i.e., Cuba. But he had time to observe that the gulf received huge and powerful currents of fresh water on which observation he built up his fantastic theory that he was at the mouth of one of the four rivers of paradise, situated at the top of the earth, the earth being not round but pear-shaped.

When Columbus arrived in Española he found that Francisco Roldán, whom he had appointed mayor of Isabela, had rebelled against his brothers in Xaraguá with about 70 followers. Bartolomé's attitude to the rebellion had been vigorous; Christopher's was temporizing. He wrote a subservient letter to Roldán; concluded an agreement with him; allowed the rebels to break it; and finally concluded a second agreement which amounted to complete surrender to Roldán, for his past was condoned and he was appointed alcalde mayor. This done, Columbus sent a messenger to Spain reporting the incident and explaining why the agreement was void since, among other reasons, he had signed it as viceroy but on board a caravel where he was not viceroy but admiral. He felt depressed, and his troubles increased with the sudden arrival (Sept. 5, 1499) of a small fleet he was not expecting. One of his youngest and most enterprising lieutenants, Alonso de Ojeda, while in Seville had heard of Columbus' discovery of pearls in Paria. He thereupon obtained from Fonseca permission to go "discovering," sailed about with varied fortunes and, when short of supplies, calmly turned up at Española. Columbus had every right to consider him as a poacher. He sent Roldán with two caravels. Ojeda listened to Roldán but went his own way to Xaraguá (Feb. 1500). Roldán followed him there. Ojeda left again, but Xaraguá's settlers, in a state of near-rebellion, had to be terrorized into obedience by a capital execution ordered by Columbus himself. The rule of Columbus then came to a sudden end.

**Columbus Removed From Command.**—Reluctantly and slowly the king and queen had come to the conclusion that Columbus was a good admiral but a bad governor. He himself had writ-

ten to them (Oct. 1498) asking for a learned man to administer justice in the new world. They chose an old member of their household with an excellent reputation, Francisco de Bobadilla, whom they gave powers strictly limited to an enquiry into the rebellion and the punishment of the rebels (March 21, 1499). A fresh batch of bad news made them go one step further, and on May 21, 1499, Bobadilla was appointed governor and chief magistrate of Española by letters patent in which no mention was made of Columbus. Bobadilla was empowered to embark for Spain any person of any rank. A special letter addressed to Columbus and his brothers enjoined them to obey and deliver to Bobadilla all royal property, castles, arms and stores. But the rest of the year went by and Bobadilla did not sail. There are strong reasons for thinking that the final decision to let him go was due to information obtained by the sovereigns of Columbus' obscure dealings, bordering on treason, with Genoese agents.

Bobadilla arrived at Santo Domingo on Aug. 23, 1500. Before the wind allowed him to land he was informed by a messenger sent out by Diego that several Spaniards had been hanged that week and five more were waiting for the gallows. He was also told that Christopher Columbus was in Concepción and Bartolomé in Xaraguá, each with a confessor to despatch guilty prisoners by the same method. On Aug. 24, Bobadilla, after mass, had his first dispatch read aloud—that appointing him enquirer into the rebellion—and asked for all prisoners to be handed over. Diego refused. Next day, after mass, he had his second dispatch read—that appointing him governor. Obstructed again, he had all his guns unmasked and revealed the royal letter enjoining him to pay all arrears of salaries, if need be, on Columbus' account. On Diego's persistent refusal, Bobadilla forced his way into the citadel and took possession of the prisoners. On Sept. 15, Bobadilla met Columbus, who refused to acknowledge his appointment on the ground that the king and queen could not deprive him of his position. Bobadilla had both him and Diego arrested and put in fetters. Bartolomé, who in Xaraguá "had 16 Spaniards in a ditch or well waiting to be hanged," was summoned to Santo Domingo and fettered. When he was brought to embark for Spain, Columbus feared that he was being conveyed to the gallows. Though he was treated with respect throughout the voyage he refused to be unfettered. Sad and with his irons still on, he landed in Cadiz toward the end of Nov. 1500. The king and queen, who were at Granada, were shocked at the news, ordered him to be set free and sent him 2,000 ducats to enable him and his brother to come to court. When Columbus saw his royal patrons, he stood dumb with emotion, fell on his knees and burst into tears.

**Attitude of the Spanish Sovereigns.**—The king and queen were sympathetic and generous, but by no means disposed to alter their view as to the political capacity of the admiral. They probably disapproved of the harsh ways of Bobadilla but not, in general, of his handling of a delicate and possibly dangerous situation. Though legally bound by their agreement with Columbus they had to consider that the land already discovered far exceeded their expectations and that he was no man to be entrusted with a government. Generous with him they could afford to be, but not at the cost of the public good. On the other hand, Columbus, now frustrated in his dreams of greatness in the new world, cast about for another grand work to achieve and found it in his biblical, prophetic mind: he would liberate Jerusalem. To that effect, he did not consult cosmographers, merchants or ambassadors. He read the prophets, and having collected all the texts he could showing that Jerusalem would be liberated by Spain, he presented his *Book of Prophecies* to the king and queen.

Meanwhile a crowd of discoverers was sailing his seas, landing in his islands and stealing his future discoveries; French and English sailors were astir: everybody seemed to be entering the business, to a point that made Columbus write bitterly: "They all made fun of my plan then; now even tailors wish to discover." That was all very well, but how was he going to liberate Jerusalem if he were not allowed to find more gold in that new world where gold was born? The king and queen were willing provided he did not return to Española; and he suggested a search for a passage through the new-discovered lands to the other seas.

**Last Voyage.**—Nicolás de Ovando, appointed governor to succeed Bobadilla, sailed for Española from Sanlúcar (Feb. 13, 1502) in command of 32 ships, 2,500 men and 12 Franciscan friars. He carried orders to restore to Columbus his property confiscated by Bobadilla. By Oct. 1501, Columbus felt confident enough to go to Seville to prepare his fourth expedition. He bought four ships of about 50–60 tons, which he thought the best size for discovery, and he selected 146 men. He left his eldest son Diego (then 21) to represent him at court, and took with him his younger boy, Fernando (then 13). He asked to be allowed to call at Española and was expressly forbidden to do so, at any rate on the way out. He sailed from Cadiz on May 9, 1502.

On May 25 Columbus began his crossing from the Canary Islands and on June 15, 1502, he discovered an island he called Matinino, one of the Lesser Antilles. A few days later he sailed straight for Santo Domingo. Ovando refused him admittance, and he left for Puerto Hermoso, 16 leagues to the west, where he sheltered from a storm. He produced pretexts for his disobedience to royal orders, but the reason was his usual stiff-necked reluctance to bow before authority; it was but natural that he should regard as his those lands he had brought to light. The ship conveying Bobadilla, Torres, Roldán, the cacique Guarionex in irons, and considerable gold was lost in the storm he weathered in Puerto Hermoso. He sailed for Jamaica on July 14, 1502, overcame a mutiny of his men, sailed along the coast of Honduras and was at Cape Gracias a Dios on Sept. 14. His men were mutinous again, but he sailed on, wandering in lands of his imagination. He wrote to the king and queen that "from there to the river Ganges there are ten days," and he referred again to the earthly paradise. Formidable storms all but smashed his ships. On Epiphany Sunday, 1503, he was pushed by the wind into a kind of estuary he named Belén (Bethlehem). As there seemed to be gold about, he resolved to leave his brother Bartolomé there with 80 men; but the natives thought otherwise and he had to give up the plan and sail away, "in the name of the Holy Trinity, on Easter night, with the ships rotten, worm eaten, all in holes. Two only remained in the same state, boatless, empty of supplies, to cross 7,000 miles of sea with a son, a brother and so many men."

On May 13, 1503, he was "in Mango province, which is next to that of Cathay, and from there I sailed towards Española." His geography remained that mixture of scientific truth and wild fantasy which his whole life incarnates. After more storms, mutinies, imprecations to God, and narrow escapes, he found himself derelict in a small cove in Jamaica (June 23, 1503) whence he wrote to the king and queen a truly magnificent letter, telling them of his perils, wanderings, dreams and voices he heard from on high, in a style worthy of the Old Testament.

**Return to Spain and Death.**—For a whole year, Columbus struggled against all his usual troubles: indiscipline, native restlessness, ill health, lack of shelter and food, doubt and disillusionment. He had sent a messenger, Diego Méndez, to ask Ovando for help. Two caravels arrived late in the spring, and at last he was able to sail for Española (June 28, 1504) and for Spain (Sept. 12). Storms pursued him again in his last crossing, but he landed safely in Sanlúcar on Nov. 7, 1504. He could hardly move and had to be conveyed to Seville; traveling north was out of the question. On Nov. 26, 1504, Queen Isabella died. Columbus hoped that she had provided in her will for him to be "restored in the possession of the Indies." His hopes were disappointed, and he wrote to his son to seek the help of King Ferdinand's men. He wrote memoir upon memoir on the Indies and their gold. Sick in body, but worse still in mind with humiliation, frustration and impatience, he was not able to move northward until May 1505, when he was received by Ferdinand in Segovia, and asked to be restored "the capital of my honour . . . the government and possession of the Indies." The king was sympathetic and willing to please Columbus and, on his suggestion, put Deza in charge of his affairs. But as a responsible monarch he could not reappoint the passionate admiral as governor of the Indies. Columbus' health went from bad to worse. He dictated his will on May 19, 1506, and died at Valladolid the following day.

After the funeral ceremonies at Valladolid, Columbus' remains

were transferred to the Carthusian monastery of Santa Maria de las Cuevas, Seville, where the bones of his son Diego were also laid. Exhumed in 1542, the bodies of both were taken to Hispaniola and interred in the cathedral of San Domingo. The remains of Christopher Columbus later rested in a tomb in the cathedral of Santo Domingo. In the 1940s, however, construction of the Columbus Memorial lighthouse, a huge monument designed as the last resting place of the great admiral, was started on a high cliff at the mouth of the Ozama river in the Dominican Republic.

In general appearance, Columbus was tall and dignified, red-haired and of a very white complexion, which reddened at the slightest excitement. His mind was lofty and imaginative, and so taut that his actions, thoughts and writings do at times suggest a man just this side of the edge of insanity.

**COLUMBUS (COLÓN), DIEGO** (c. 1480–1526), eldest son of Christopher Columbus (q.v.), was born on the island of Porto Santo. When his father undertook the great voyage of discovery in 1492, Diego was made page of Prince Juan, heir to the thrones of Ferdinand and Isabella. His marriage to Doña María Álvarez de Toledo, after the death of his father, helped him obtain confirmation as admiral of the Indies and governor of Hispaniola. He took up his governorship in 1509 but continued the family suit against the crown for restoration of all the discoverer's privileges. This was settled in 1536 after his death. During his governorship of Hispaniola a controversy over the status of the Indians broke out and he left for Spain in 1515 to defend himself, leaving his wife in charge. He returned to the island in 1520 but had to go to Spain for further negotiations in 1523. He died in Spain in Puebla de Montalbán on Feb. 24, 1526.

See Samuel Eliot Morison, *Admiral of the Ocean Sea: a Life of Christopher Columbus*, 2 vol. (1942). (U. S. L.)

**COLUMBUS**, a city of Georgia, U.S., and seat of Muscogee county, is situated 95 mi. S.S.W. of Atlanta at the head of navigation on the Chattahoochee river. Population according to the 1960 census was 116,779. In early times the site of the city was the focal point of several Indian trading posts. Founded in 1828, Columbus was on the main route of westward migration and was also the centre of a potentially rich agricultural area which later produced cotton, livestock and peanuts. It grew rapidly into a commercial and industrial community, becoming a leading textile centre by 1840. Its mills were the first to operate by hydroelectric energy, generated at the nearby fall line. During the American Civil War Columbus was an important source of Confederate ordnance, producing artillery, swords, guns, uniforms and two gunboats. It was captured by Gen. James H. Wilson on April 16, 1865, and its factories suffered a small measure of destruction.

The Columbus standard metropolitan statistical area (Chattahoochee and Muscogee counties in Georgia and Russell county in Alabama) had a 1960 population of 217,985. (For comparative population figures see table in *GEORGIA: Population*.) This area continues to be one of the leading industrial centres of the south, the textile industry alone operating nearly 400,000 spindles. Other leading manufactures are brick, tile, concrete pipe, fertilizer, ice-making and refrigerating machinery, agricultural implements, sugarcane mills, engines, boilers, shafting and pulleys, lumber products, food processing, meat packing, textile machinery, bank and office furniture, automobile batteries and many complementary smaller industries.

Columbus is the trading centre of the 22 surrounding counties comprising the Chattahoochee valley. Widely known for its public school system, Columbus was the first city in Georgia to establish municipal graded schools, and among the earliest in the south to provide industrial training as part of its public school system.

Near Columbus is Ft. Benning, one of the largest army posts in the U.S., with a military reservation of about 189,000 ac.

Columbus established a commission-manager form of government in 1922. The city has 17 public parks, 2 public libraries, a public museum of arts and crafts and a symphony orchestra. Columbus junior college, established in 1958, is operated by the University System of Georgia. (Js. C. B.)

**COLUMBUS**, a city of Indiana, U.S., seat of Bartholomew county, is 42 mi. S.E. of Indianapolis. It was laid out in 1821 and called Tiptonia in honour of John Tipton who had donated 30 ac., but a month later it was renamed Columbus. It was incorporated as a town in 1839. Ohio, Kentucky, Pennsylvania and New York made substantial contributions to the early population.

Columbus is a diversified industrial community surrounded by productive land. Industries include the manufacture of diesel engines, castings, variable-speed transmissions, radio and electronics components, metal furniture, leather, men's clothing, die sinking and tool making. A Purdue University extension centre is located there.

For comparative population figures see table in INDIANA: *Population*. (E. W. H. L.)

**COLUMBUS**, a city of northeastern Mississippi, U.S., seat of Lowndes county, is located 9 mi. from the Alabama border, 169 mi. S.E. of Memphis and 122 mi. W. of Birmingham. It was founded in 1821 on a high bluff overlooking the Tombigbee river. The steamboat "Cottonplant" first landed in Columbus in 1822, as at that time the city was a port of entry. Many beautiful ante-bellum homes dot the Columbus landscape and a pilgrimage for tourists is held every spring.

Agriculture long dominated the Columbus area, but diversified industry balances the economy and stimulates growth. Manufactures include men's clothing, automatic electric equipment, drainboards, bricks, compressed cotton, ornamental stone, automobile plates, furniture, lumber and creosoted ties.

Established in 1884, Mississippi State College for Women became the first state-supported college in the United States exclusively for women. Franklin academy, founded in 1821, is the oldest free public school in Mississippi.

For comparative population figures see table in MISSISSIPPI: *Population*. (E. H. Hs.)

**COLUMBUS**, the capital and third largest city of Ohio, U.S., the seat of Franklin county, is situated centrally in the state on the relatively flat Ohio till plain. It is a planned political centre created by an act of the legislature in 1812 to be located on the east bank of the Scioto river. Its political functions remain important, but it has gained respect as a commercial, industrial and educational centre as well. Pop. (1960) city 471,316, reflecting an increase of 25.4% over 1950; standard metropolitan statistical area (Franklin county) 682,962, an increase of 35.7% over 1950. (For comparative population figures see table in OHIO: *Population*.) Columbus annexed extensively after 1950: its area in 1960 was 89 sq.mi. compared to 39.4 sq.mi. in 1950, an increase of 125.9%. The trend of suburbanization is emphasized by the sharp percentage of increases in population in the communities of Upper Arlington, Whitehall, Worthington, Hilliards and smaller communities and townships lying on the urban fringe. Delaware and Pickaway counties were added to the S.M.S.A. in 1965.

The federal government organized surveys of the "Ohio country" in 1785, and in 1787 enacted the Ordinance for the Northwest Territory. Later, land grants were offered in Ohio to satisfy the varied claims of participants in the American Revolution. Included was a grant to Virginia of extensive lands west of the Scioto river. Early Virginian surveys into the area resulted in the village of Franklinton in 1797 on the west bank of the river.

The Ohio general assembly, in seeking a permanent site for the state capital, accepted the offer of land speculators for acreage on the east bank of the river in the refugee tract (a land grant established by the U.S. congress for the benefit of Canadian sympathizers of the American Revolution). A capitol, penitentiary and several other government buildings were constructed upon 20 ac. of donated land. A city plan was developed by Joel Wright, state director of planning, and the first sale of lots oc-

curred on June 18, 1812. By 1824, Columbus had replaced Franklinton as the county seat.

Growth was slow with fewer than 700 persons in the city in 1815. By 1840, following the extension of the National Road and the opening of a feeder branch of the Ohio and Erie canal into the city, the population exceeded 6,000. With the exception of the decade 1850-60, substantial population increases were recorded reflecting the city's emergence as a rail and commercial centre. By 1900 the population reached 125,560.

After 1950 increases in population and area surpassed the growth rates of the previous five decades. This resulted partially from the unprecedented industrial development occurring after 1940. The location of a large aircraft plant in the city in 1941 was an initial stimulus but additional plants, often large branches of national organizations, were also attracted to the city. In the second half of the 20th century there were approximately 800 manufacturing plants employing 76,800 workers in the city. Even so, this was only 28% of the total work force, the lowest ratio of manufacturing employees to total work force in any major Ohio city. In part, this emphasizes the diversified activities present. Among the leading industrial plants in Columbus are branches of national organizations manufacturing airplanes, automobile parts, and electrical equipment and appliances, as well as local organizations engaged in the manufacture of machinery, glass, coated fabrics, shoes, fire-fighting equipment and food products. The city's favourable geographical position is enhanced by the presence of five major railroads, an extensive highway network and the airport, Port Columbus, which is 7 mi. E. of the downtown district. Columbus serves a 12-county retail trade area, accounting for two-thirds of all retail business in the area.

Approximately 12% of the work force is employed by some governmental agency. The federal government operates the world's largest military depot in Columbus, as well as Lockbourne air force base, Ft. Hayes and other facilities. Many of the state's welfare institutions and numerous state offices, the penitentiary, fairgrounds and the capitol are present. An attractive civic centre, one block west of the commercial core, includes city hall, a veterans' memorial hall (an exhibition hall and auditorium seating 4,000), Central high school, various state and federal offices and the 555.5 ft.-high Lincoln-LeVeque tower, the city's only skyscraper.

The city supports the Columbus Gallery of Fine Arts and the Columbus Symphony orchestra. Ohio State university (1870) occupies an attractive campus 4 mi. north of the downtown section. The university is a land grant institution with more than 90 departments of instruction, including medical, law and graduate schools. Other major educational institutions include Capital university (1850) including the Evangelical Lutheran Theological seminary, Otterbein college in Westerville (Evangelical United Brethren, 1847) as well as Franklin university, a branch of the Columbus Y.M.C.A., and College of St. Mary of the Springs (1868) and Josephinum Pontifical college. Battelle Memorial institute, private industrial research organization, began operations in 1929; its research in metallurgy and mineral industries is world renowned. Present also are the Orton Ceramic foundation, Nalin laboratories, local branches of national research organizations and research-oriented university functions, such as the research foundation of Ohio State university.

Columbus has more than 1,000 ac. in parks, including city parks, playgrounds, a metropolitan park system along sections of the rivers and public parks associated with reservoir areas. The water supply is obtained from three dams: Griggs, built in 1905; O'Shaughnessy, built in 1925 on the Scioto river; and Hoover, completed in 1955 on the Big Walnut creek. (H. L. Hu.)

**COLUMELLA, LUCIUS JUNIUS MODERATUS** (1st century A.D.), Roman soldier and farmer, who wrote extensively on agriculture and kindred subjects in the hope of arousing a love for farming and a simple life. A Spaniard by birth, from Gades in southwestern Spain, he became in early life a tribune of the Legio VI Ferrata which was stationed in Syria, but neither an army career nor the law attracted him and he took up farming, successfully, in Italy.

The *De re rustica* in 12 books which is his second and fuller treatment of farming and country life has survived; also a treatise *De arboribus* which was part of the earlier work. The subjects of the first nine books of the *De re rustica* are general precepts, land and crops, vines, land dimensions, trees and livestock including birds, fishes and bees. The 10th book, on gardening, was written in hexameters as a supplement to the *Georgics* of Virgil. It is carefully written but Columella had no poetic gift. This was intended to close the work but, to fulfill a promise to a friend, Columella added the 11th book, on the duties of a bailiff, on what work must be done in each month of the year and on the culture of gardens and garden herbs. The 12th book concerns the choice and duties of a bailiff's wife.

Columella was an experienced farmer; he had an attractive enthusiasm for his calling and great pride in it. His style is neat, lucid and sober and he avoids technicalities as far as is compatible with giving necessary information.

In addition to his extant works Columella wrote the lost *Aduersus astrologos*. He intended to write a work on rituals followed in farming, but whether he did so is not known.

**BIBLIOGRAPHY.**—Edition by J. G. Schneider in vol. ii of his *Scriptores rei rusticae veteres Latini* (1794); also in the "Loeb Series," with Eng. trans. (1941–55); a critical edition begun by V. Lundström in 1897 and published in Sweden still lacks books 3, 4, 5 and 12. See also Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, x, 1054–1068 (1917); W. E. Heitland, *Agricola*, pp. 250–269 (1921).

(G. B. A. F.)

**COLUMN**, in architecture, a general term for any vertical structural support; particularly, the monumental pillars in a portico or colonnade. The base (*q.v.*) and capital (*q.v.*) are usually considered parts of the column; a column and entablature (*q.v.*), considered as an architectural unit, form an order.

The monumental column evolved from primitive prototypes constructed of short-lived materials, the character of which persisted as a stylistic tradition when large buildings came to be built of permanent materials. In Mesopotamia primitive columns were made of bundled reeds and mud; by 3000 B.C. they were covered with small glazed tiles, which provided waterproofing and a decorative system. Similarly, the columns of ancient Egyptian architecture probably evolved from primitive types, as indicated by the prevalent decorative system of reeds, stems, buds and blooms, all translated into stone. The largest Egyptian examples (69 ft. high) were erected (c. 1300 B.C.) in the great temple at Karnak, where the columns were laid up in large sections (drums) and were decorated with intaglio and colour. Polychromatic and sculptural characteristics also evolved in stone columns in Persian and in Indian architecture; the lacquered wooden columns of China and Japan also displayed these characteristics.

In Europe the first columns were crude wooden posts. Inverted tree trunks were doubtless the primitive origin of the downtapering columns at Knossos and Mycenae (c. 1300 B.C.). The Greeks, however, reversed the taper, gradually substituted stone for wood, and finally produced the Doric order, which attained classical perfection in the Athenian Parthenon (begun 447 B.C.). The Doric column consisted of capital and shaft, which was usually constructed of drums, although monoliths or brick and stucco sometimes were used. The shaft was usually fluted and the profile refined by subtle curvature (see *ENTASIS*). Ionic and Corinthian columns, developed later, were characterized by slender proportions, sculptured capitals, and the addition of a base.

Roman columns were adapted from Greek precedent, influenced by wooden Etruscan prototypes. They appeared freestanding in colonnades, as in Greece, although more characteristically the Roman column was engaged to a square pier supporting an arch, as on the Colosseum (finished A.D. 82).

Secondhand Roman columns were frequently used in Early Christian churches, from the 4th century onward; and basic Roman forms, with modifications, were perpetuated in Byzantine, Romanesque and Gothic architecture. External usage in Romanesque and Gothic was restricted largely to the church portal, where clustered columns were often enriched with statues; e.g., at Chartres and Amiens cathedrals. The Renaissance marked the revival of pure Roman forms, especially the engaged column with

pier and arch, best characterized in the 16th-century Farnese palace, Rome, although there were numerous variations. The free-standing column in portico and colonnade reappeared in the 17th century (two early instances being the twin churches in the Piazza del Popolo, Rome, and the east façade of the Louvre, Paris) and became common in the 18th and 19th centuries, when the memorial column, as a civic monument, was also revived from Roman antiquity.

The Industrial revolution produced cheap imitations of historical styles in cast-iron columns, which were used extensively by the 1850s. From this development emerged the system of metal-frame construction, notably in Chicago of the 1880s, leading to further developments in steel (e.g., the H-column). The structural system employing reinforced-concrete columns had also evolved by the end of the 19th century. Despite some attempts to modernize historical columns, the most significant developments after 1900 were conditioned by new materials and new structural concepts. See *ORDER*; see also references under "Column" in the Index volume.

(E. A. C.)

**COLUMNIST**, the author or editor of a regular, signed contribution to a newspaper, usually under a permanent title and devoted to comment on some aspect of the contemporary scene. The column may be humorous or serious, on one subject or on life in general, frivolous in tone or heavily freighted with good advice on manners, morals or other subjects of interest. Essentially a column is a reflection of the writer's individual tastes and point of view, whether it is concerned with women's hats, foreign policy or the stock market.

The word columnist is recent and U.S., apparently dating from about 1920, but columns came earlier. The late 19th century saw the development in the U.S. of humorous miscellanies frequently featuring contributions from readers. Among the pioneers in this form were Eugene Field (*q.v.*) and Bert Leston Taylor. In the early 20th century the role of the columnist who presided over these collections of diverse elements became more defined, and the modern column emerged. In the 1920s columns proliferated in many fields, including politics, economics, books, movies, society, medicine, homemaking, sports and contemporary life and ideas. National syndication of columns increased rapidly; in the latter half of the 20th century there were over 400 in the U.S. A great number of these were devoted to commentary on public affairs. At the same time, newspapers ranging from eight-page weeklies to metropolitan dailies recognized the value of the "personal touch" provided by their own columnists.

Writing a column requires, in addition to knowledge of the subject matter, ability to project a personality, ability to find an audience and to establish rapport with it. The columnist's subject matter is frequently ephemeral in interest and may appeal to a limited geographic area as well. His work is therefore highly transitory for the most part, but at its best it fulfills an important educational function—and it is often a favourite feature with readers of the newspaper in which it appears.

**COLURE**, in astronomy, either of the two principal meridians of the celestial sphere (*q.v.*), one of which passes through the poles and the two solstices, the other through the poles and the two equinoxes; hence designated as solstitial colure and equinoctial colure, respectively.

**COLUTHUS** (*COLLUTHUS*) or *LYCOPOLIS* in the Egyptian Thebaid (fl. c. A.D. 500), Greek epic poet, is represented by one extant poem, *The Rape of Helen*, which was discovered by Cardinal Bessarion (c. 1395–1472) in Calabria. This poem of 394 hexameters is in imitation of Homer and Nonnus and tells the story of Paris and Helen from the wedding of Peleus and Thetis down to the elopement and arrival at Troy. According to the Suda lexicon he was also the author of *Calydoniaca* (probably an account of the Calydonian boar hunt); *Persica* (an account of the Persian wars); and *Encomia* (laudatory poems in epic verse). These are all lost.

**BIBLIOGRAPHY.**—W. Weinberger, *Tryphiodori et Colluthi carmina*, "Teubner Series" (1896); *Opptian, Colluthus and Tryphiodorus*, with Eng. trans. by A. W. Mair, "Loeb Series" (1928); Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, xi, 2 (1921).

(J. M. Hy.)

**COLVIN, SIR SIDNEY** (1845–1927), English literary critic and connoisseur of art, whose scholarship particularly illuminated his work on Keats, was born in London on June 18, 1845. He was educated at Cambridge. In 1873 he became Slade professor of fine art at Cambridge, and was director of the Fitzwilliam museum from 1876 to 1884, when he became keeper of prints and drawings at the British museum. In 1873 he formed a lasting friendship with Robert Louis Stevenson, and in 1895 published *Vailima Letters*, Stevenson's letters to him from Samoa. He also edited Stevenson's works, and two further volumes of his letters. Colvin's *Keats* (1887) marked an advance in the study of the poet. He recognized the quality and importance of Keats's letters, and prepared a selection of them in 1891. He published many works on fine art, and his *Memories and Notes of Persons and Places* appeared in 1921. He died in London on May 11, 1927.

See E. V. Lucas, *The Colvins and Their Friends* (1928).

(P. M. Y.)

**COLWYN BAY** (BAE COLWYN), a municipal borough (1934), in the Denbigh parliamentary division of Denbighshire, Wales, on the Irish sea, 41 mi. W.N.W. of Chester by road. Pop. (1961) 23,090. The town grew rapidly after 1918, until it became virtually continuous with Old Colwyn and Rhos-on-Sea, with which it is linked by a promenade 3 mi. long around the sandy bay. It is a seaside resort and a centre for excursions in north Wales and has an industrial diamond factory. Rydal school for boys was founded in 1885. To the southeast (2½ mi.) is Llanellian-yn-Rhôs, famous for its "cursing well" (Ffynnon Elian). The name Colwyn is that of the lords of Ardudwy, in west Merionethshire.

**COLY**, a small group of African birds about 12 in. long, with crested heads, finchlike bills, rounded wings and long tails. Six species are all included in the genus *Colius*, which constitutes the peculiar order Coliiformes and family Coliidae of the Ethiopian region. Although they are most closely related to hummingbirds and trogons (*q.v.*), they appear very different from them. The sexes are similar in appearance, being generally of a dun or slate colour, but sometimes marked with white or chestnut. Colies are often called mousebirds, probably from their habit of creeping along the boughs of trees with the whole tarsus of the foot applied to the branch. The toes are very long, and the first one is reversible; *i.e.*, it can be directed forward or backward. Colies are gregarious and notably acrobatic. They often hang head downward and are reputed to sleep in that position. The voice includes harsh calls, mewing cries and whistling notes. They feed principally on vegetable matter, but occasionally take insects. The nest, placed above the ground, is a shallow cup of twigs and bark lined with soft materials. Both parents incubate the two to seven usually pure white eggs.

(E. R. BE.)

**COLZA OIL**, a nondrying or semidrying oil, also called rape oil or rapeseed oil. It is obtained from the seeds of a turniplike plant that is cultivated in France, Belgium, the Netherlands and Germany.

See OILS, FATS AND WAXES.

**COMA** is a complete loss of consciousness from which the subject cannot be aroused by various stimuli. It is a symptom of various disease states. It is often associated with convulsive attacks and may be transient or prolonged.

Coma requires prompt medical treatment. First aid is bodily

quiet and comfort with warmth and cleanliness. Free access of air is vital as the relaxation of the jaw and tongue may interfere with proper breathing. See also articles under various diseases such as DIABETES.

(F. L. A.; X.)

**COMA BERENICES** ("Berenice's Hair"), in astronomy, a small constellation between Leo and Boötes, first mentioned in the 3rd century B.C. It is said to represent the hair of an Egyptian queen, placed by her as an offering in a temple of Venus. The distinguishing feature of this constellation is the Coma cluster, a galactic cluster of stars, which is faintly visible to the naked eye and which marks the position of the north pole of the Milky Way.

(R. H. BR.)

**COMANA**, an ancient city of Cappadocia, the site of which lies at Shahr, a village in the Anti-Taurus mountains on the upper course of the Seyhan (Sarus) river, about 20 mi. downstream from the little town of Sariz in the Adana (Seyhan) *il* of Turkey. Frequently called Chryse, or Aure (*i.e.*, the golden), to distinguish it from Comana in Pontus, it was celebrated as the place where the rites of Ma-Enyo, a variety of the great west Asian nature goddess, were celebrated with orgiastic rites of an Anatolian character.

The service was carried on in a sumptuous temple with great magnificence by many thousands of *hierodouloi* (temple servants). To defray expenses, large estates were set apart, which yielded a more than royal revenue. The city, a mere appanage of the temple, was governed immediately by the chief priest, who was generally a member of the reigning Cappadocian family and took rank next to the king. The number of persons engaged in the service of the temple, even in Strabo's time (63 B.C.–c. A.D. 21), was upward of 6,000, and among these, to judge by the names common on local tombstones, were many Persians. Under the emperor Caracalla, Comana became a Roman colony, and it received honours from later emperors down to the official recognition of Christianity. The place derived importance in antiquity from its position at the eastern end of the main pass of the western Anti-Taurus range, through which passed the road from Caesarea Mazaca (Kayseri) to Melitene (Malatya), converted by Septimius Severus into the chief military road to the eastern frontier of the empire. The extant remains at Shahr include a theatre on the left bank of the river, a fine Roman doorway and many inscriptions; but the exact site of the great temple has not been satisfactorily identified.

See P. H. H. Massy, "Exploration in Asiatic Turkey, 1896–1903," *Geogr. J.* (Sept. 1905); E. Chantre, *Recherches archéologiques dans l'Asie occidentale. Mission en Cappadoce* (1898).

(D. G. H.; Wm. C. B.)

**COMANA**, an ancient city of Pontus, traces of which are visible near the village of Gumenek on the Yesil Irmak, 7 mi. N.E. of Tokat in the Tokat *il* of Turkey. The mother goddess Ma-Enyo was worshiped in the city with rites like those employed at Comana in Cappadocia, whence the city was said to have been colonized. There were 6,000 slaves attached to the temple. The high priest in Roman times was a rich and autonomous landlord.

(Wm. C. B.)

**COMANCHE**, a warlike Indian tribe of the southern Great Plains of the United States, closely related to the Wind River Shoshone of Wyoming and the Northern Shoshone of the Great Basin (see SHOSHONE). In speech, they belong to the Uto-Aztecan (*q.v.*) linguistic stock.

Evidence indicates that the immediate ancestors of the Comanche occupied the Yellowstone river country in the 17th century. As the Blackfoot, Crow, Arapaho, Cheyenne and Dakota tribes pushed westward, the Comanche moved south along the edge of the plains into western Texas. They are first reported in New Mexico, in 1705. They early became possessors of numerous horses and were one of the first tribes to develop the pattern of equestrian nomadism that became so characteristic of the Plains Indians in the 18th and 19th centuries.

The Comanche drove the Apache from the southern plains, and in 1790 and 1840 they entered into formal alliances with the Kiowa and Cheyenne (*q.v.*), respectively. Raids for booty and captives carried the Comanche as far south as Durango in north central

ARTHUR W. ANBLER FROM NATIONAL AUDUBON SOCIETY

RED-FACED COLY (*COLIUS INDICUS*)

Mexico. Comanche resistance blocked the westward expansion of the Texas frontier for nearly half a century.

The social organization of the Comanche lacked lineages, clans, military societies and tribal government. The 13 or so bilateral bands were nontotemic and politically autonomous. The Comanche did not possess the sun dance (*q.v.*) or any other integrating tribal ceremonial prior to 1874. They also lacked the communal buffalo hunt so characteristic of other Plains Indians.

Although a reservation of nearly 3,000,000 ac. in the present state of Oklahoma was assigned to the Comanche, Kiowa and Kiowa-Apache in the Medicine Lodge treaty of 1867, the Comanche wars with the United States did not end until June 1875. The Kiowa-Comanche reservation was broken up into individual allotments in July 1901. In 1945, 2,700 Comanche were living on their individual holdings in the vicinity of Lawton, Okla. See also PLAINS INDIANS.

**BIBLIOGRAPHY.**—E. A. Hoebel, *The Political Organization and Lawways of the Comanche Indians*, American Anthropological Association Memoir 54 (1940); R. N. Richardson, *The Comanche Barrier to South Plains Settlement* (1933); E. Wallace and E. A. Hoebel, *The Comanches: Lords of the South Plains* (1952). (E. A. HL.)

**COMAYAGUA**, department in central Honduras. Pop. (1961) 96,420; area 2,006 sq.mi. Although consisting mostly of highlands, the department has several fertile valleys and produces coffee, tobacco, rice, yucca, beans, corn and cattle; it is also significant in swine, poultry, vegetable and fruit production.

Comayagua city, the departmental capital (pop. 8,456) founded in 1540 on the right bank of the Humuya river, lies in a fertile valley 32 mi. long and 16 mi. wide. It served as the Spanish colonial capital of the province of Honduras under the name of Valladolid la Nueva. The town was burned by revolutionaries in 1827, when it had a population of 18,000. It also served as the capital of the republic until 1880, when it was replaced by Tegucigalpa. Comayagua has a handsome cathedral built in 1715, other public buildings dating from colonial times, and several small industries.

The city is 65 mi. from Tegucigalpa by way of the modern Inter-Ocean highway, which extends northwestward to beautiful Lake Yojoa along the eastern shore and on to Potrerillos, where it connects with the railway to the north coast at Puerto Cortés.

(C. F. J.)

**COMAYAGUELA:** see TEGUCIGALPA.

**COMB** is a toothed toilet implement used for cleaning and arranging the hair, and also for holding it in place after it has been arranged; the word is also applied, from resemblance in form or in use, to various appliances employed for dressing wool and other fibrous substances, to the indented fleshy crest of a cock and to the ridged series of cells of wax filled with honey in a beehive.

Hair combs are of great antiquity, and specimens made of wood, bone and horn have been found in Swiss lake dwellings. Among the Greeks and Romans they were made of boxwood, and in Egypt also of ivory. For modern combs the same materials are used, as well as tortoise shell, metal, India rubber, celluloid and other synthetic plastic materials.

There are two chief methods of modern manufacture. A plate of the selected material is taken of the size and thickness required for the comb, and on one side of it, occasionally on both sides, a series of fine slits are cut with a circular saw. This method involves the loss of the material cut out between the teeth.

The second method, known as twinning or parting, avoids this loss and is also more rapid. The plate of material is rather wider than before, and is formed into two combs simultaneously, by the aid of a twinning machine. Two pairs of chisels, the cutting edges of which are as long as the teeth are required to be and are set at an angle converging toward the sides of the plate, are brought down alternately in such a way that the wedges removed from one comb form the teeth of the other, and that when the cutting is complete the plate presents the appearance of two combs with their teeth exactly dovetailing into each other. In India-rubber combs the teeth are molded to shape and the whole hardened by vulcanization.

**COMBAT FATIGUE** (also called flying, operational, pilot, convoy and battle fatigue, or combat exhaustion), a term commonly used in World War II to designate states of (1) hypersensitivity to stimuli such as noises, movements and light accompanied by

overactive responses that include "startle reactions" with involuntary defensive jerking or jumping; (2) easy irritability progressing even to acts of violence; (3) sleep disturbances including battle dreams, nightmares and inability to fall asleep. Although persons in combat differed widely in their susceptibility to combat fatigue because of hereditary factors and previous training, most cases resulted from exposure to physical hardship, fatigue and emotional conflicts. The emotional conflicts usually were related to loss of comrades, leaders and group support, together with other precipitating events in the battle setting. Most patients were treated with best results near the front lines by being given rest, food and sedation, provided they were permitted to stay with their units.

**COMBE, ANDREW** (1797–1847), Scottish physician, an advocate of phrenology and a pioneer of popular health education, was born in Edinburgh on Oct. 27, 1797. While studying in Paris he came under the influence of J. C. Spurzheim, the founder with F. J. Gall of the pseudo science of phrenology, and in 1820 Andrew and his brother George (1788–1858) founded the Phrenological society. He acquired an extensive practice in Edinburgh but was handicapped by ill-health. In 1836 he was appointed physician to King Leopold of Belgium, but soon returned to Edinburgh. In 1838 he became physician-extraordinary to the queen in Scotland. Combe wrote *The Principles of Physiology Applied to the Preservation of Health* (2nd ed., 1834), *The Physiology of Digestion* (1836) and *A Treatise on the Physical and Moral Management of Infancy* (1840). He died at Gorgie, near Edinburgh, on Aug. 9, 1847.

See George Combe, *Life and Correspondence of Andrew Combe* (1850).

(W. J. Br.)

**COMBE, WILLIAM** (1741–1823), English writer, the creator of "Dr. Syntax," was born in Bristol in 1741. Many details of his life are obscure, though Combe, a brilliant talker, is the hero of scores of anecdotes. He was educated at Eton; then, having been left a legacy by a rich London merchant, William Alexander (who may have been his father), he traveled widely and lived "in a princely style"—whence his nickname of "Count Combe." He fell heavily into debt, and after a varied career as private soldier, waiter, teacher and cook, returned to London about 1771 and took to writing for a living. He died at Lambeth on June 19, 1823.

An able journalist and voluminous writer, Combe has at least 84 works to his credit, besides numerous periodical articles, sermons, etc. Nothing, however, appeared under his own name in his lifetime. In 1789 he was given £200 annually for his pamphleteering support of William Pitt; and about 1797 he became an editor of *The Times*. The most successful of his earlier works were a vituperative verse satire, *The Diaboliad* (1776), and a prose "continuation" of Le Sage (*q.v.*), called *The Devil Upon Two Sticks in England* (1790). His fame, however, rests upon his "Dr. Syntax," written originally (1809–11) for Ackermann's *Poetical Magazine* to accompany plates by Thomas Rowlandson (*q.v.*). Reprinted in 1812 as *The Tour of Dr. Syntax in Search of the Picturesque*, it went into nine editions by 1819 and was one of the most popular books of the early 19th century. It was followed by *Tours* "in Search of Consolation" (1820) and "in Search of a Wife" (1821). In all, the three *Tours* comprise over 25,000 lines of octosyllabic couplets, undistinguished in style, sententious and sentimental; yet they have a certain charm, score some fair satiric hits and are still readable. Combe also co-operated with Rowlandson in *The English Dance of Death* (1815–16), which contains some of his best verse, and *The Dance of Life* (1816).

See *Gentleman's Magazine*, obituary (Aug. 1823) and a list of works (May 1852); *Times Literary Supplement* (July 19, 1941).

(R. P. C. M.)

**COMBES, (JUSTIN LOUIS) ÉMILE** (1835–1921), French statesman responsible for the separation of church and state, was born at Roquecourbe, Tarn, on Sept. 6, 1835. Destined for the priesthood, he studied at the seminary at Castres and at the Ecole des Carmes in Paris. A doctor of divinity, he published his thesis *La Psychologie de Saint-Thomas d'Aquin* (1860) and taught philosophy at the Collège de l'Assomption at Nîmes. Being refused ordination, Combes studied medicine and became a doctor in 1867.

He practised at Pons (Charente-Inférieure) where he became mayor in 1875. A member of the Grand Orient de France, he sat with the predominantly masonic Radical party when he was elected senator in 1885. He was appointed minister of education and of cults under Léon Bourgeois (1895–96). He actively supported Waldeck-Rousseau's ministry and upon its retirement was himself charged on June 7, 1902, with the formation of a government which became one of the longest in the third republic. He took the portfolios of the interior and of cults and devoted himself to the rigorous application of the Associations law of 1901 (see WALDECK-ROUSSEAU, PIERRE MARIE RENÉ).

At the age of 67, Combes preserved something of his clerical training in a dogmatic combativeness to which he had added all the prejudices of the republican anticlerical. He took a simple view of his duties; he was delegated by the republican majority to extirpate the clerical menace and was determined to finish, once and for all, with "the enemies of the republic." A great number of Roman Catholic schools were shut, and Combes proposed to authorize only five religious orders; for the others, authorizations were refused en bloc. Then even the authorized orders were assailed, but the few remaining teaching orders among them were allowed ten years' further life (law of July 1904 suppressing schools directed by a religious congregation). The Vatican's protest against President Loubet's visit to Rome in March 1904 was published by *L'Humanité* in May, despite the cabinet's efforts to keep it secret, and the ensuing crisis enabled Combes to table legislation in October for the separation of church and state. This became law in Dec. 1905; but Combes had already resigned office on Jan. 18, after the split of the supporting coalition over the allegation that the personal staff of the war minister, Gen. Louis André, regularly received reports (the so-called *fiches de délation*) from the masonic Grand Orient de France on all officers suspected of reactionary opinions or of clericalism.

Combes sat as minister without portfolio in Briand's cabinet of 1915–16 and died at Pons on May 25, 1921. His works include *Une campagne laïque* (1904); *Une deuxième campagne laïque* (1905); and *Mon ministère 1902–05* (1956).

**COMBINATION IN INDUSTRY:** see MONOPOLY; CARTEL.

**COMBINATION LAW**, the name given to the British acts of 1799 and 1800 which made trade unionism illegal. The law, as finally amended, sentenced to three months in jail or to two months' hard labour any workman who combined with another to gain an increase in wages or a decrease in hours, or who solicited anyone else to leave work or objected to working with any other workman. The sentence was to be imposed by two magistrates and appeal was forbidden unless "two sufficient sureties in the penalty of £20" were given, which was most unlikely since anyone contributing to the expenses of a person convicted under the act would be fined £10, and the recipient another £5. The removal of a conviction by a writ of certiorari was forbidden, and defendants could be forced to bear witness against each other. Other clauses forbade employers' combinations, but these were never in any recorded case put into operation. The laws were repealed in 1824 as a result of the patient intrigue of the radical tailor, Francis Place (*q.v.*), acting through Joseph Hume, M.P. The repeal was followed by a rash of strikes and in 1825 an unsuccessful attempt was made to reimpose the acts. See also LABOUR [TRADE] UNION; Great Britain; LABOUR LAW.

(R. W. P.; X.)

**COMBINATORIAL ANALYSIS**, a branch of mathematics which deals with problems of arrangements or designs. As examples may be cited: (1) the problem of arranging a bridge tournament so that each player will have every other player as partner the same number of times and as opponent the same number of times; and (2) the problem of arranging  $n^2 + n + 1$  points into  $n^2 + n + 1$  sets of  $n + 1$  points so that these sets will be the lines of a projective plane; i.e., so that any pair of distinct points will lie on exactly one line. There may be a time element in the prob-

lem; for example, it may be required to schedule the use of tankers to transport specified quantities of oil so as to minimize the time consumed in delivery and reduce the number required.

In a problem of arrangement or design there are generally two natural questions: (1) Can it be done at all? (2) If so, in how many ways? In some problems the existence of at least one solution is trivial and the interest lies almost entirely in the number of ways in which the problem can be solved. These are problems of enumeration. Occasionally it may happen that the best way of finding that an arrangement is possible is to derive a formula giving the number of solutions. And, of course, procedures for constructing arrangements and designs are relevant to both questions.

It is difficult to subdivide combinatorial analysis into clear-cut sections; however, there are four major subdivisions which include most of the subject. These are: (1) permutations and combinations; (2) theorems on choice; (3) theory and construction of designs; (4) minimal and maximal choices.

**Permutations and Combinations.**—In how many ways can two letters be selected from  $x, y, z$ ? This naturally depends on whether it is permissible to choose the same letter twice and whether the order of the two letters chosen matters. If order is counted and repetition is allowed there are 9 choices:

$$xx, xy, xz, yx, yy, yz, zx, zy, zz$$

If order is counted but repetition disallowed there are only 6 choices:

$$xy, xz, yz, yx, zx, zy$$

If repetition is allowed but order not counted there are 6 choices:

$$xx, yy, zz, xy, xz, yz$$

If order is not counted and repetitions are not permitted there are only 3 choices:

$$xy, xz, yz$$

A selection in which order counts is called a permutation; a selection in which order does not count is called a combination.

The number of permutations of  $n$  objects  $x_1, \dots, x_n$  taken  $r$  at a time with repetitions permitted is  $n^r$ , since in a choice  $a_1 a_2 \dots a_r$  there are  $n$  possibilities for  $a_1$ , and for each choice of  $a_1$  there are  $n$  choices for  $a_2$ , and so on for each of  $a_3, \dots, a_r$ . If repetitions are not permitted then there are still  $n$  choices for  $a_1$ , but for  $a_2$  there are only  $n-1$  choices since the object chosen as  $a_1$  may not be chosen again. Having chosen  $a_1 a_2$ , there are now  $n-2$  choices for  $a_3$ . More generally, having chosen  $a_1 a_2 \dots a_{i-1}$  there are  $n-i+1$  choices for  $a_i$ . Hence for a permutation of  $n$  things taken  $r$  at a time,  $a_1 a_2 \dots a_r$ , there are  $n(n-1)(n-2) \dots (n-r+1)$  choices. This number is frequently written  ${}_nP_r$ . It is convenient to use the factorial notation  $n!$  for the product  $1 \cdot 2 \cdot 3 \dots (n-1)n$  for a positive integer  $n$ . Thus,  $6! = 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 = 720$ . By definition,  $0! = 1$ . Now

$$n! = 1 \cdot 2 \cdot 3 \dots (n-1)n = n(n-1)!,$$

thus  $(n-1)! = n!/n$  for any positive integer  $n$ . In this notation it will be seen that  ${}_nP_r = n!/(n-r)!$ .

A particular set of  $r$  distinct objects  $b_1, b_2, \dots, b_r$  chosen from  $n$  distinct objects  $x_1, x_2, \dots, x_n$  will give  $r!$  permutations  $a_1 a_2 \dots a_r$ , since  $a_1$  may be any one of the  $r$  objects  $b_1, \dots, b_r$ ,  $a_2$  may be any one of the  $r-1$  remaining and so on. Hence each combination of  $n$  objects taken  $r$  at a time without repetition gives exactly  $r!$  permutations of the  $n$  objects taken  $r$  at a time without repetition. Also, each of the  ${}_nP_r$  permutations arises exactly once from a combination. Letting  ${}_nC_r$  denote the number of combinations of  $n$  things taken  $r$  at a time without repetition, it has been shown that  ${}_nP_r = r! \cdot {}_nC_r$ , whence  ${}_nC_r = n!/(n-r)!r!$ . The numbers  ${}_nC_r$  are the binomial coefficients arising in the formula

$$(x+y)^n = \sum_{r=0}^n {}_nC_r x^r y^{n-r},$$

since in a product of  $n$  factors  $(x+y)(x+y) \dots (x+y)$  the coefficient of  $x^r y^{n-r}$  is the number of ways of choosing  $y$  from  $r$  of the factors and  $x$  from the rest.

What can be said about the number of combinations of  $n$  things

taken  $r$  at a time with repetitions permitted? To find this number, a trick is employed. Suppose it is desired to find the number of combinations of 5 letters  $a, b, c, d, e$  taken three at a time, with repetitions permitted. Of the  $8 = 5 + 3$  numbers  $0, 1, 2, 3, 4, 5, 6, 7$ , take a combination of three of the 7 numbers  $1, 2, 3, 4, 5, 6, 7$ . One such combination is  $3, 4, 7$ . Now list 0 through 7, replacing the chosen numbers  $3, 4, 7$  by  $x$ 's. This gives  $0\ 1\ 2\ x\ x\ 5\ 6\ x$ . Now replace the remaining numbers by the letters  $a, b, c, d, e$  in order. This gives  $a\ b\ c\ x\ x\ d\ e\ x$ . From this pattern, a combination is obtained by taking each letter as many times as it is followed by an  $x$ , in this case the combination  $c\ c\ e$ . Conversely, a combination of three of the letters, repetitions permitted, determines in this manner a unique combination of three of  $1, \dots, 7$  without repetitions. Thus  $a\ a\ d$  gives the pattern  $a\ x\ x\ b\ c\ d\ x\ e$  corresponding to the combination  $1, 2, 6$ . The above argument may be generalized to the case of combinations of  $n$  things taken  $r$  at a time with repetitions permitted, the number of these being  ${}_{n+r-1}C_r$ . In the example under discussion, the number of combinations of 5 letters taken three at a time with repetitions permitted is  ${}_{7+3}C_3 = 7!/4!3! = 7 \cdot 6 \cdot 5 / 1 \cdot 2 \cdot 3 = 35$ . Since the value of  $n!$  increases so rapidly with  $n$ , complete lists of combinations or permutations cannot in practice be written down except for small values of  $n$  or  $r$ .

**Discordant Permutations.**—A permutation of  $n$  objects taken  $n$  at a time will be called more briefly a permutation. Of the  $n!$  permutations of  $n$  objects it may be desired to find the number satisfying certain restrictions. Some problems have a natural formulation in terms of restricted permutations. Suppose it is desired to find the number of ways  $n$  married men may choose their  $n$  wives as dancing partners so that no man dances with his own wife. If the husbands are numbered arbitrarily as  $1, 2, \dots, n$  and if the  $i$ th husband dances with the wife of husband  $a_i$ , then  $a_1 a_2 \dots a_n$  is a permutation of  $1, 2, \dots, n$  in which the restriction  $a_i \neq i$  is imposed. Clearly, the number of these "discordant" permutations is the answer to the problem. The calculation of this number may be made by the celebrated Principle of Inclusion and Exclusion. Consider  $N$  objects and  $n$  properties  $1, 2, \dots, n$ . Let  $N_i$  be the number of objects with property  $i$ ,  $N_{ij}$  the number with properties  $i$  and  $j$ , and more generally  $N_{i_1 i_2 \dots i_k}$  the number with all properties  $i_1, i_2, \dots, i_k$ . If  $N(0)$  is the number with none of the properties  $1, 2, \dots, n$ , the Principle of Inclusion and Exclusion asserts that

$$N(0) = N - \sum_i N_i + \sum_{i < j} N_{ij} - \sum_{i < j < k} N_{ijk} + \dots + (-1)^s \sum_{i_1 < i_2 < \dots < i_s} N_{i_1 i_2 \dots i_s} + \dots + (-1)^n N_{123 \dots n}$$

An object with none of the properties is counted above once in  $N$  and not at all in the remaining terms. An object with exactly one property  $i$  is counted  $+1$  times in  $N$  and  $-1$  times in  $-\sum_i N_i$

and thus, in all, is counted a total of 0 times on the right. Similarly, an object with exactly  $r$  of the properties is counted  $+1$  times in  $N$ ,  $-r$  times in  $-\sum_i N_i$ ,  $r(r-1)/2$  times in  $+\sum_{i < j} N_{ij}$  and

$(-1)^s {}_rC_s$  times in  $(-1)^s \sum_{i_1 < \dots < i_s} N_{i_1 i_2 \dots i_s}$ . Hence this ob-

ject is counted in all  $1 - r + {}_rC_2 - {}_rC_3 + \dots + (-1)^s {}_rC_s + \dots + (-1)^r {}_rC_r = (1-1)^r = 0$  times, since the coefficients  ${}_rC_s$  are the binomial coefficients. To find the number of discordant permutations, let  $N = n!$  be the total number of all permutations of  $1, \dots, n$  and let the  $i$ th property of a permutation  $a_1 \dots a_n$  be the property that  $a_i = i$ . Here  $N(0)$  is the number of discordant permutations. It is clear that  $N_{i_1 i_2 \dots i_s} = (n-s)!$ , and thus the number of discordant permutations turns out to be

$$N(0) = n! - n \cdot (n-1)! + [n(n-1)/2](n-2)! - \dots + (-1)^s [n(n-1) \dots (n-s+1)/s!](n-s)! + \dots = n! \left[ 1 - 1 + \frac{1}{2!} - \frac{1}{3!} + \dots + \frac{(-1)^n}{n!} \right]$$

This is the integer nearest to  $n!/e$ , where  $e = 2.71828 \dots$  is the well-known base of natural logarithms.

The "problème des ménages" is a more complicated problem of the same kind. Given a circular table with  $2n$  seats, it is required to find the number of ways of seating  $n$  couples with gentlemen and ladies alternating so that no husband sits on either side of his wife. Clearly, the ladies may be seated in  $2(n!)$  ways. Now number the wives  $1, 2, \dots, n$  in a clockwise fashion and also assign the number  $i$  to the empty seat to the right of the  $i$ th wife. Then the  $i$ th husband may not sit in either of the seats numbered  $i$  or  $i+1$ . Hence if the number of the husband sitting in the  $j$ th seat is  $a_j$ , then  $a_1 a_2 \dots a_n$  is a permutation discordant with both  $1\ 2\ 3 \dots n$  and  $2\ 3\ 4 \dots n1$ . The number of such permuta-

tions, the "ménage number," is  $U_n = \sum_{k=0}^n \frac{(-1)^{k+1} 2n}{2n-k} \binom{2n-k}{k}$

$(n-k)!$ . The solution of the ménage problem and many others of a similar kind may be found in the book by John Riordan listed in the bibliography.

**Partitions.**—A subject at first sight independent of permutations but in fact almost identical with it is that of partitions. This topic is a phase of the general subject of distributions, being the theory of combinations of summands having a given sum. For compactness in display, it is convenient to formulate the typical problem as follows: In how many ways can the number  $m+n$  be represented as the sum of exactly  $n$  positive integers? Thus for  $n=4$ ,  $m=2$ , there are

$$6 = 3 + 1 + 1 + 1 = 2 + 2 + 1 + 1,$$

two ways, and for  $n=2$ ,  $m=4$ , there are  $6 = 5 + 1 = 4 + 2 = 3 + 3$ , three ways. The following table was prepared by Leonhard Euler, who studied the recursion relations among the values of this function.

$n$	$m=0$	1	2	3	4	5	6	7	8	9	10	11	...
$m=0$	1	1	1	1	1	1	1	1	1	1	1	1	...
1	1	1	1	1	1	1	1	1	1	1	1	1	...
2	1	2	2	2	2	2	2	2	2	2	2	2	...
3	1	2	3	3	3	3	3	3	3	3	3	3	...
4	1	3	4	5	5	5	5	5	5	5	5	5	...
5	1	3	5	6	7	7	7	7	7	7	7	7	...
6	1	4	7	9	10	11	11	11	11	11	11	11	...
7	1	4	8	11	13	14	15	15	15	15	15	15	...
8	1	5	10	15	18	20	21	22	22	22	22	22	...
9	1	5	12	18	23	26	28	29	30	30	30	30	...
10	1	6	14	23	30	35	38	40	41	42	42	42	...

With this partition function denoted by  $P(n, m)$ , the relations of Euler (1764) are:  $P(1, m) = P(n, 0) = P(n, 1) = 1$ ,  $P(n, m) = 0$ , ( $m < 0$ ),  $P(n, m) = P(n-1, m) + P(n, m-n)$ ,  $P(n, m) =$

$\sum_{s=1}^n P(s, m-s)$ , and those of M. A. Stern (1840) are

$$P(n, m) = P(n-1, m) + P(n-1, m-n) + P(n-1, m-2n) + P(n-1, m-3n) + \dots$$

From the simplest tactical considerations (N. M. Ferrers, 1853) of the horizontal rows and vertical columns of a *point diagram* (also called *lattice diagram* or *graph*) such as the following, an important general theorem may be inferred. In this case there are twenty points arranged in horizontal rows containing 5, 4, 4, 3, 2, 2 points and in vertical columns containing 6, 6, 4, 3, 1 points:

.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.

Studies of such diagrams helped to establish the Theorem of Reciprocity (J. J. Sylvester, 1882): *Every partition of  $n$  into  $k$  positive summands, of which the greatest is equal to  $h$ , determines a reciprocal partition of  $n$  into  $h$  positive summands, of which the greatest*

*is equal to  $k$ .* The following are immediate corollaries: *The number of partitions of  $n$  into  $k$  parts is equal to the number of partitions of  $n$  into parts of which the largest is  $k$ ; and, The number of partitions of  $n$  into not more than  $k$  parts is equal to the number of partitions of  $n$  with no part greater than  $k$ .*

The number of partitions of  $n$  into any number of parts is written  $p(n)$ . In the above table,  $p(n) = P(n, n)$ . Associated with

$p(n)$  is the generating function  $f(x) = \sum_{n=0}^{\infty} p(n)x^n$ . It can be

shown easily that  $f(x) = (1-x)^{-1}(1-x^2)^{-1}(1-x^3)^{-1} \dots$ . An interesting identity due to Euler is the following:

$$\frac{1}{f(x)} = (1-x)(1-x^2)(1-x^3) \dots = 1 + \sum_{k=1}^{\infty} (-1)^k x^{(3k^2-3k)/2}$$

A combinatorial proof of this identity, using the Ferrers' graph, was obtained by J. Franklin in 1881. From the identity,  $p(n)$  may be calculated recursively using  $p(0) = 1$  and  $p(n) = p(n-1) + p(n-2) - p(n-5) - p(n-7) + \dots + (-1)^{k-1} \{p[n - (3k^2-k)/2] + p[n - (3k^2+k)/2]\}$ . The function  $f(x)$  belongs to the class of elliptic modular functions. These functions satisfy a large variety of identities, of which the Euler identity is typical. Using these, G. H. Hardy and Srinivasa Ramanujan showed in 1918 that  $p(n)$  is approximately  $\frac{1}{4n\sqrt{3}} \exp(\pi\sqrt{\frac{2n}{3}})$ . In 1937 H. Rademacher improved this approximation to give an exact value.

**Theorems on Choice.**—Suppose that there are  $n$  subsets  $S_1, S_2, \dots, S_n$  of  $N$  objects ( $N$  finite), and that differently labeled subsets  $S_i$  and  $S_j$  are allowed to contain the same objects (see SET THEORY [THEORY OF AGGREGATES]). Under what circumstances can distinct representatives  $a_1, \dots, a_n$ ,  $a_i \in S_i$ ,  $i = 1, \dots, n$  be chosen; i.e.,  $a_i \neq a_j$  if  $i \neq j$ ? The following condition is clearly necessary: For  $k = 1, 2, \dots, n$ , any  $k$  of  $S_1, \dots, S_n$  shall contain between them at least  $k$  distinct objects. Philip Hall showed in 1935 that this condition is also sufficient when either  $N$  or  $n$  is finite. Marshall Hall showed in 1948 that if  $m$  is the smallest number of objects in any  $S_i$  then the number of choices of distinct representatives is at least  $m!$  if  $m < n$  and at least  $m(m-1) \dots (m-n+1)$  if  $m > n$ . He also (in 1956) formulated an algorithm which either constructs a system of distinct representatives or produces  $k$  subsets containing between them less than  $k$  objects. The theorem of Philip Hall has been generalized in various ways to infinite systems, but the above condition is not sufficient if both  $N$  and  $n$  are infinite.

A theorem due to D. König is somewhat like Philip Hall's theorem. Consider an  $m \times n$  matrix  $A$ , and let a "line" of  $A$  mean either a row or column. The entries in  $A$  are numbers and the only distinction is between zero entries and nonzero entries. The theorem of König asserts that the minimum number of lines which together contain all nonzero entries is the same as the maximum number of cells which can be chosen with nonzero entries such that no two of them are on a line. The theorem of König is equivalent to the theorem of Philip Hall in the sense that either theorem can easily be proved as a consequence of the other.

A further theorem on choice is Ramsey's theorem: Let  $S$  be a set containing  $N$  elements and suppose that the family  $T$  of all subsets of  $S$  containing exactly  $r$  elements is divided into two mutually exclusive families  $\alpha$  and  $\beta$ . Let  $p \geq r$ ,  $q \geq r$ ,  $r \geq 1$ . Then if  $N \geq n(p, q, r)$ , a number depending solely on the integers  $p, q, r$  and not on the set  $S$ , it will be true that there is either a subset  $A$  of  $p$  elements, all of whose  $r$  subsets are in the family  $\alpha$ , or there is a subset  $B$  of  $q$  elements, all of whose  $r$  subsets are in the family  $\beta$ . If  $r = 2$ , Ramsey's theorem can be applied to graphs in the following manner. With  $N$  points, each pair of points is joined by an arc and each arc is coloured with one of two colours ( $\alpha$  or  $\beta$ ). Then if  $N$  is sufficiently large there is either a set of  $p$  points all of whose arcs are of colour  $\alpha$  or a set of  $q$  points all of whose arcs are of colour  $\beta$ . In 1955 A. Gleason and R. Greenwood generalized this problem to include any number of colours. They proved the theorem corresponding to Ramsey's and indeed found very sharp limits

on the magnitude of  $N$  in many instances.

**Theory and Construction of Designs.**—A basic kind of design is a Latin square. This is an  $n \times n$  square in which each of the numbers  $1, 2, \dots, n$  occurs exactly once in each row and exactly once in each column. Two Latin squares are regarded as being essentially the same if one may be obtained from the other by performing a substitution on the numbers and permuting rows and columns appropriately. With this convention there is only one square for  $n = 2$  or  $3$ , and two for  $n = 5$ . The two for  $n = 5$  are

1	2	3	4	5	1	2	3	4	5
2	3	4	5	1	2	1	4	5	3
3	4	5	1	2	3	4	5	1	2
4	5	1	2	3	4	5	2	3	1
5	1	2	3	4	5	3	1	2	4

Two  $n \times n$  Latin squares are said to be orthogonal if, when one is superimposed upon the other, every pair of digits occurs once and only once. A number of Latin squares are said to be mutually orthogonal if any two of them are orthogonal. For example, here are three mutually orthogonal  $4 \times 4$  squares:

1	2	3	4	1	2	3	4	1	2	3	4
2	1	4	3	3	4	1	2	4	3	2	1
3	4	1	2	4	3	2	1	2	1	4	3
4	3	2	1	2	1	4	3	3	4	1	2

The largest possible number of mutually orthogonal Latin squares is easily seen to be  $n - 1$ . A set of  $n - 1$  mutually orthogonal squares is called a complete set of orthogonal squares. A complete set of orthogonal squares is exactly equivalent to a finite affine plane with  $n^2$  points. Suppose the squares to be superposed, and regard each of the  $n^2$  cells as a point. A total of  $n + 1$  sets of parallel lines may be passed through these points in the following way. The first set will consist of the rows of the square, the second of the columns. For  $i = 3, \dots, n - 1$  the  $i$ th set is formed from the  $(i - 2)$ nd square. A line of the  $i$ th set shall consist of those points (cells) which in the  $(i - 2)$ nd square all carry the same number. The  $n^2$  points and the  $n + 1$  sets of parallel lines form a finite affine plane. By reversing the foregoing procedure a finite affine plane may be used to construct a complete set of orthogonal squares.

For  $n$  odd it is easy to construct a pair of  $n \times n$  orthogonal squares. For example, in cell  $(i, j)$  put  $i + j \pmod{n}$  in the first square and  $i + 2j \pmod{n}$  in the second square. Having done this it is not very difficult to construct a pair of orthogonal  $n \times n$  squares when  $n$  is a multiple of 4. But for  $n \equiv 2 \pmod{4}$  the situation is different. Trivially there are no orthogonal  $2 \times 2$  squares. In 1779 Euler tried unsuccessfully to construct a pair of  $6 \times 6$  orthogonal squares and conjectured that no pair of orthogonal squares exists for  $n \equiv 2 \pmod{4}$ . By systematic trial G. Tarry showed in 1901 that no  $6 \times 6$  orthogonal squares exist. In 1959 the Euler conjecture was exploded in a most conclusive manner by the joint efforts of R. C. Bose, S. Shrikande and E. T. Parker. Except for  $n = 2$  and  $n = 6$  Euler was proved entirely wrong. A pair of  $n \times n$  squares exists for every larger  $n$ . The following pair of  $10 \times 10$  squares, given in superposed position, was found by Parker:

00	47	18	76	29	93	85	34	61	52
86	11	57	28	70	39	94	45	02	63
95	80	22	67	38	71	49	56	13	04
59	96	81	33	07	48	72	60	24	15
73	69	90	82	44	17	58	01	35	26
68	74	09	91	83	55	27	12	46	30
37	08	75	19	92	84	66	23	50	41
14	25	36	40	51	62	03	77	88	99
21	32	43	54	65	06	10	89	97	78
42	53	65	05	16	20	31	98	79	87

Among other designs the block designs (full name: balanced incomplete block designs) have been most thoroughly studied. A

block design is an arrangement of  $v$  distinct objects into  $b$  blocks, where each block contains exactly  $k$  distinct objects, each object appears in exactly  $r$  different blocks and a pair of distinct objects occurs together in exactly  $\lambda$  blocks. These five parameters trivially satisfy the two conditions

$$bk = vr, r(k - 1) = \lambda(v - 1)$$

The first of these conditions counts occurrences of objects in blocks in two ways; the second counts pairs involving a particular object in two ways. If  $k = 3, \lambda = 1$  the design is called a Steiner triple system. Here  $v$  is easily shown to be of the form  $6m + 1$  or  $6m + 3$  and  $r = (v - 1)/2, b = v(v - 1)/6$ . In 1852 J. Steiner proposed the construction of these systems and in 1859 M. Riess showed by a constructive method that there is a Steiner triple system for every  $v$  of the form  $6m + 1$  or  $6m + 3$ .

It is true, though not obvious, that  $b \geq v$ . If  $b = v$  then  $k = r$  and  $k(k - 1) = \lambda(v - 1)$ . In this case, the designs are called symmetric designs. A special case of the symmetric designs is that in which  $\lambda = 1$ . These are the finite projective planes, which are of great interest in their own right. The most important theorem on symmetric designs is the result of the combined work of H. Ryser, R. Bruck and S. Chowla. Using the Hasse-Minkowski theorems on rational quadratic forms, they showed that if a symmetric design exists with parameters  $v, k, \lambda$  satisfying the elementary condition  $k(k - 1) = \lambda(v - 1)$ , then (1) if  $v$  is even then  $k - \lambda$  is a square and (2) if  $v$  is odd then the equation  $x^2 = (k - \lambda)x^2 + (-1)^{(v-1)/2} \lambda y^2$  has solutions in integers  $x, y, z$  not all zero. This shows, for example, that with  $\lambda = 1$ , if  $k - \lambda = 6, 14, 21, 22$  or any one of infinitely many other values, no design exists. These necessary Bruck-Ryser-Chowla conditions may conceivably be sufficient, but this is a long way from being known.

**Minimal and Maximal Choices.**—Two problems involving minimal and maximal choices are known as the assignment problem and the traveling-salesman problem. The first has been solved, but the second has not. The assignment problem involves finding a method for assigning  $n$  men to  $n$  jobs, given a table of  $n^2$  numbers  $a_{ij}, i, j = 1, \dots, n$ , where  $a_{ij}$  is a score representing the value of placing the  $i$ th man in the  $j$ th job. The optimum assignment maximizes the sum of the scores of the assignments. In the traveling-salesman problem,  $n$  cities and  $n(n - 1)/2$  transportation costs between cities are given. The problem is to arrange a trip for the salesman going through every city and returning to his starting point so as to minimize the transportation cost. The assignment problem may be solved by an appropriate use of the theorem of König. Both these problems can be considered as belonging to a class of problems in which a certain expression (usually linear) must be maximized or minimized subject to certain conditions (usually linear inequalities). A duality theorem due to D. Gale, A. W. Tucker and H. W. Kuhn is of great value in many of these problems. Many problems of combinatorial analysis, in particular the theorems of König and Philip Hall, can be solved by these techniques. This newest part of combinatorial analysis can be expected to develop considerably. See also NUMBERS, THEORY OF; PROBABILITY, MATHEMATICAL.

**BIBLIOGRAPHY.**—M. Hall, Jr. et al., *Combinatorial Analysis* (1960); P. A. MacMahon, *Combinatory Analysis*, 2 vol. (1960); J. Riordan, *An Introduction to Combinatorial Analysis* (1958). (M. H.)

**COMBINE.** The term "combine" is in popular use throughout Great Britain and the Dominions as a synonym for what is more commonly spoken of in the United States as a "merger." It is employed to denote the large and probably monopolistic concern which results from the permanent "combination" of a number of smaller concerns in the same line of business. The combine is one form of industrial consolidation. (See MONOPOLY.)

In the United States, the term is widely used to denote a machine that harvests, threshes and cleans grain in the field. See HARVESTING MACHINERY.

**COMBINE HARVESTER:** see HARVESTING MACHINERY.

**COMBING** is a process applied to wool fibres in the manufacture of worsted yarn, as distinguished from woolen yarn, and to superior grades of cotton in the production of fine cotton yarn. Regardless of the kind of fibre treated, the purpose is to lay the

fibres parallel, remove dirt and nibs, and eliminate short fibre lengths. Other processing in yarn manufacture contributes to fibre parallelization and removal of foreign matter, but combing is unique in its function of fibre selection. Combed stock with its more uniform fibre lengths permits the spinning of yarns of finer diameters, greater strength in relation to size, and more lustre and evenness than are obtainable from uncombed material.

**Development.**—The processing of wool is such an ancient art, predating recorded history, that it is not possible to determine when combing first became an integral part of wool manufacture. But since the patron saint of wool combers is St. Blasius, who was martyred early in the fourth century, it can be presumed that the craft dates at least from medieval times. As a handicraft it persisted until the mid-19th century, the complexity of the operation resisting all efforts to mechanize it despite the pressures exerted by the successful mechanization of spinning and weaving and the consequent demand for a greater volume of combed stock.

In the household and handicraft stage combing was accomplished with two hand combs. Handfuls of cleaned, oiled wool were lashed into the teeth of the combs, which were then heated in a comb pot. One when withdrawn was affixed at a convenient height to a "pad post" and with the second in hand the comb was then passed the teeth of one through the tuft of wool on the other. By making each in turn the working comb the fibres were gradually smoothed and straightened until the longer combed fibres could be drawn off in the fingers and laid out as a sliver a few feet in length. The short fibres (noils) remaining in the comb heads were collected separately and sold as stock for the manufacture of woolen yarns.

The first successful development in machine combing came near the close of the 18th century through the ingenuity of an English clergyman, Edmund Cartwright. In his first model, called the "Big Ben," he placed a series of hand combs on the exterior of a drum revolving around a horizontal axis in such a manner as to engage and clear out wool held in a fixed, upright comb. Recognizing the limitations imposed by the necessity for recharging the fixed comb with stock, Cartwright later substituted for it a circular comb revolving around a vertical axis. Since wool could be lashed into this supply comb without interrupting the combing action it was possible to produce a nearly continuous sliver of combed material. These machines were of limited practical application because they produced excessive amounts of noils and could not be used for handling fine wools; yet they are notable in that they employed the principles later incorporated in the most widely adopted types of machine combing.

Improvements in combing were introduced in the first half of the 19th century by four English inventors: George Donisthorp and Samuel Cunliffe Lister, who produced the nip-motion comb; Isaac Holden, who with Lister developed the square-motion comb, and James Noble, who with Donisthorp originated the circular or Noble comb. During this same period Joshua Heilman, an engineering student of Mulhouse, France, also patented a nip-motion comb in response to a prize offered by a cotton manufacturer of Alsace. Heilman, whose machine was known as the rectilinear and later as the French comb, succeeded in establishing prior patent rights to the nip-motion principle and brought action against Lister for infringement. The latter was forced to buy out the rights for production in England and in consequence its sale there was suppressed until 1900.

The two forms most widely used have been the Noble comb associated with the Bradford, or English, system of spinning worsted yarns and Heilman's, which was commonly incorporated in the French system of worsted spinning and in the cotton industry. (See WOOL.)

**English Method.**—The Noble comb employs a large circular comb within which are two smaller circular combs having a diameter less than the radius of the larger circle. The two smaller combs are placed opposite each other and tangential to the inner edge of the larger circle, thus forming two combing positions. Sliver from supply packages on the exterior of the large circle is led over the point where large and small circles touch and is tamped into the combs. As the larger and smaller combs rotate in the

same direction their arcs diverge and a fringe of combed stock extends from the inner edge of the large circle and the outer edge of the small circle. This fringe is drawn off by rollers, joined with the similar product from the second combing position and fed out of the machine as a continuous strand of combed top. The short fibres (noils) remaining in the teeth of the small circles are cleared and collected separately. As the larger circle revolves, the supply sliver in the space between the combing positions is lifted, moved forward and tamped down again as it reaches the next combing position.

**French Method.**—In the French comb the material to be combed is fed in a narrow sliver to a position just above a roll having combing teeth set in one segment of its circumference. Nippers then engage the sliver, holding it fast while the revolving comb engages and clears out that portion of the sliver lying ahead of the nippers. The nippers then rise and drawing-off rollers engage the combed fringe, pulling it through a straight comb that has dropped into the sliver behind the raised nippers. In this fashion a tuft of combed wool is produced, the revolving comb having acted on the first portion and the latter part having been pulled through the straight comb. These tufts are then overlaid and condensed to produce a continuous delivery of combed sliver from the machine.

**World-Wide Trade.**—The combed top, the product of combing, is accumulated in large balls and in this form, ready for dyeing and for worsted spinning, it becomes a commodity traded extensively in world markets with prices quoted on established exchanges for its immediate and future delivery. Combing normally is applied only to very fine cottons and better-grade wool fibres because the lower grades of stock are not suited for treatment and also because the process increases the sales price of the product since it is an added operation and a significant portion of stock is rejected in the form of noils.

(H. C. Wz.)

**COMB JELLY**, a common name for small marine invertebrates constituting the phylum Ctenophora. These common denizens of the sea are free swimmers with transparent, gelatinous bodies equipped with comblike plates. Not infrequently comb jellies have been confused in the popular mind with the true jellyfishes (medusae of Coelenterata), but in their structure, actions and evolutionary position they are very different from the coelenterates. Some of the 80 or more known species can live in brackish water, but most live only in full-strength sea water, none can withstand fresh water.

**Distribution and Natural History.**—*Geographical Range.*—Among the comb jellies *Pleurobrachia pileus* (commonly known as sea gooseberry, sea walnut or cat's eye) and the larger *Beroë cucumis* are cosmopolitan in distribution; they have been found in all the seas of the world, from the tropics to the polar regions. Most species are more restricted in their range, however. Individual species may be tropical, temperate, boreal or polar. Although the majority of the ctenophores occur in coastal areas and in the more superficial layers of water, some species live in the middle of the oceans as well, and specimens have even been collected at depths up to 9,800 ft. (3,000 m.).

*Size, Shape and Colour.*—Most comb jellies are oval or spherical and range between 0.2 and 0.8 in. (5 to 20 mm.) in length. A few become adults, however, when only 0.1 in. long (e.g., *Tinerfe cyanea*). At the other extreme are some species of *Beroë* that reach a length of about 3.6 in. *Mnemiopsis* species, the lobed comb jellies common along the Atlantic coast of North America, may reach 4 in. (fig. 1). Even larger are *Eucharis multicornis*, which attains about 10 in., and the giant *Venus' girdle*, *Cestum veneris* (see fig. 2) of the Mediterranean, which stretches out to a flattened band as long as 4.5 ft. (1.5 m.). Most of the common comb jellies are more or less colourless, although *Beroë cucumis* is pink and *Cestum veneris* is a delicate violet colour. The colourless species are as transparent as glass, so that except for a beautiful iridescence of their swimming organs (the comb plates) they are invisible when suspended in the water. Many species are so extremely delicate that they are

GEORGE G. LOWER

FIG. 1.—SWIMMING LOBED COMB JELLIES (MNEMIOPSIS)

torn to shreds when captured in nets. These forms escape destruction during storms by descending from the turbulent surface waters to the calmer, lower layers.

**Modes of Living.**—Frequently comb jellies occur in vast swarms, especially in bays, lagoons and other coastal waters. Except for a few creeping species and parasitic species, the comb jellies all float freely suspended in the water, where they swim about feebly by means of their comb plates. They are often carried about willy-nilly by the currents (*i.e.*, they are planktonic). Except for one parasitic species, all of them are carnivorous, devouring myriads of other small planktonic animals, such as copepods, larval shrimps, various small worms, free-swimming larval

stages of oysters and clams, etc., as well as the floating eggs and fry of many fishes. It is not unusual to find, when ctenophores are locally abundant, that they have swept the water almost clear of other planktonic animals. By their predation upon larval fish and upon the larvae of species of shellfish and crustaceans valued by man, they are of great direct economic importance to man. By their extensive destruction of the planktonic animals that serve

FROM CHUN "CTENOPHORA" IN "FAUNA UND FLORA DES GOLFES VON NEAPOL"

FIG. 2.—VENUS' GIRDLE (CESTUM VENERIS)

as food for the young fry of most fishes and for the adults of other fishes (herrings, sardines, etc.), the comb jellies are of even greater indirect economic importance. In turn the comb jellies are consumed by the adults of many fishes. Direct evidence for this is lacking: because of the delicate nature of their bodies, ctenophores have seldom been reported from analyses of fish stomachs. Nevertheless, larval stages of intestinal tapeworms of fishes have been observed in some ctenophores; it is thought that entry of these parasites into the fishes could occur only by the larval tapeworms being swallowed along with the ctenophore host.

Most, and perhaps all, of the comb jellies are luminescent, some of them exhibiting a nocturnal display of bluish or greenish light that is among the most brilliant and beautiful known in the animal kingdom. The luminescence begins only after the animals have been in the dark for at least 20 minutes and the ability to luminesce is terminated by a short exposure to light. Because of their brilliance, it is almost certain that ctenophores were known to the ancients, but nowhere in the records of antiquity is there any clear distinction between the luminescence of the comb jellies and that of the true jellyfish.

## Structure and Function.—

**External Features.**—The most primitive existing comb jellies are forms such as *Pleurobrachia* and *Hormiphora* (order Cydippida). The body of *Pleurobrachia* is more or less spherical (fig. 3). At one end (oral) is a mouth and at the opposite end (aboral) a complex sense organ called the statocyst (fig. 4). The latter consists of a cluster of small calcareous (limy) concretions called statoliths attached to four groups of fused cilia. These structures are incased by a dome of fused cilia called the bell. Eight regularly placed longitudinal rows of movable comb-like plates pass from near the aboral pole toward the mouth. Each comb plate is formed by the fusion of a row of large, powerful cilia. It is from these comb plates that the phylum name, Ctenophora (from the Greek meaning comb-bearing) is derived. Swimming is accomplished by the beating of the comb plates in co-ordinated waves from the aboral to the oral end. The effective stroke of each plate is toward the aboral end, so that the animal swims as a rule with the mouth forward. However, the direction of swimming may be reversed when the animal is stimulated (mechanically or otherwise) in the oral region.

Between the rows of comb plates on opposite sides of the body are two deep pockets, the tentacle sheaths, at the base of each of which is attached a long tentacle with numerous short branches. The two tentacles can be retracted completely into their sheaths, or they can be extended widely to form a highly efficient food-gathering device. On the tentacles are numerous peculiar cells, the lasso cells or colloblasts; these cells are unique to the ctenophores. The outer border of each colloblast is covered with tiny droplets of an extremely adhesive secretion to which stick any small animals that happen to hit the tentacles. From time to time the tentacles are carried to the mouth, where the captured prey is removed and ingested. It is thought that the prey is quieted by a poison before it is swallowed.

**Digestion and Excretion.**—The mouth leads into a wide pharynx lined with a continuation of the surface (ectodermal) cells. From the pharynx two main canals pass toward the bases of the tentacle sheaths. These canals branch and form twelve smaller, blind canals, the entire complex constituting the digestive system. A blind canal lies beneath each of the eight rows of comb plates

FIG. 3.—STRUCTURE OF PLEUROBRACHIA PILEUS

(A) Whole animal, showing the two feathery tentacles, four of the eight rows of comb plates, sense organ at upper end and internal canals seen through the transparent body; (B) adhesive cell (colloblast); (C) diagram of transverse section

FIG. 4.—SENSE ORGAN OF PLEUROBRACHIA, SHOWING STATOCYST (MASS OF STATOLITHS) WITH SUPPORTS

(the meridional canals), two lie parallel to the pharynx (pharyngeal canals) and two pass along the tentacle sheaths (tentacular canals). In addition, another large canal passes aborally to the vicinity of the sense organ and opens to the outside by two tiny anal pores. All these canals are lined with digestive epithelium (endoderm). Preliminary digestion of the food takes place in the pharynx through the action of digestive secretions. Particles of partially digested food are then carried through the various canals to all parts of the body. Digestion is completed within the food vacuoles of individual endodermal cells. Elimination of indigestible material takes place mostly through the mouth, as in the coelenterates, but some passes out also through the anal pores.

**Mesogloea.**—The bulk of the body of *Pleurobrachia*, as in the other ctenophores and in most coelenterates, consists of a jellylike mass of material, called mesogloea, lying between the thin ectodermal and endodermal layers of cells. As in the higher coelenterates the cells (mesenchyme) in most of this layer are sparsely distributed. However, in at least some portions of the jelly a number of specialized muscle cells are often arranged in bundles. These muscles regulate the size of the mouth, move the tentacles, etc. This organization constitutes a great advance over the structure of the coelenterate body. The scattered mesenchyme cells and the muscle cells together form a true third layer of cells, called the mesoderm, such as is found in all the higher groups of animals.

**Nerve Network.**—Co-ordination of the activities of the animal is accomplished through a primitive network of nerve cells, comparable in many respects to that of the coelenterates. Although there is no centralization of nerve cells, the network is more concentrated beneath the rows of comb plates. Some of the co-ordination of the body is destroyed when the aboral sense organ is surgically removed.

**Reproduction and Development.**—Reproduction is sexual, that is, by the fusion of sex cells or gametes (eggs and sperms). A single ctenophore produces both eggs and sperm in the endodermal lining of the meridional canals. Investigation has shown that the sex cells, earlier believed to be emitted through the mouth, are actually released by partial rupture of the meridional canals and the body covering over these canals. Fertilization and embryonic development occur in the water.

Embryonic development of ctenophores differs greatly from that of coelenterates in several important respects (see EMBRYOLOGY AND DEVELOPMENT, ANIMAL: *Invertebrate Development*). In *Pleurobrachia* and in other Cydippida development is direct, with no larval stage occurring. More highly evolved ctenophores have a so-called cydippid larva which undergoes a metamorphosis to form the adult. Only in the parasitic *Gastrodres* has a planula larva comparable to that of the coelenterates been reported.

### CLASSIFICATION

**Ordinal Characteristics.**—*Pleurobrachia* is a representative of the primitive order Cydippida. In the order Lobata (which includes *Bolinopsis* and *Mnemiopsis*) the tentacles are greatly reduced and the oral lobes greatly enlarged. The body is somewhat flattened laterally. In the order Cestida the body is greatly extended, forming a thin band. Tentacles are very small in the adults. The cestids include the beautiful Venus' girdle mentioned earlier. In the order Beroida (*Beroë*) the tentacles are lacking, the rows of comb plates are short and the digestive canals are highly branched.

The greatest modification of all from the primitive condition occurs in the members of the order Platyctenea. In these species the body is orally aborally flattened in the adults, and in *Coeloplana* (see fig. 5) and *Ctenoplana* the animals creep around, either on the underside of the surface film of the water or upon the bottom and other solid surfaces. The ciliated bands are reduced or absent in the adults. Sperms pass to the outside through special sperm ducts that open on the aboral surface. In the Platyctenea also are to be found the largely immobile *Tjalfiella*, which is parasitic or commensal on the outer surface of some of the sea pens (anthozoan coelenterates), and *Gastrodres*, an internal parasite of salps (tunicates).

FROM L. H. HYMAN, "THE INVERTEBRATES," VOL. 1, AFTER DAWYDOFF

FIG. 5.—ADULT COELOPLANA MESNILI, SHOWING FLATTENED BODY ADAPTED TO CREEPING

extensive development of mesogloea between the ectoderm and the endoderm and by the reported existence of a planula larva (characteristic of coelenterates) in the ctenophore *Gastrodres*.

The creeping species of Platyctenea have suggested to some authorities that the ctenophores are transitional forms lying between the coelenterates and the turbellarian flatworms (phylum Platyhelminthes). Although there is a superficial similarity between the body of the Platyctenea (e.g., *Coeloplana*) and the free-living flatworms and a certain similarity in some aspects of their embryonic development, many fundamental differences between them make it improbable that the ctenophores lie directly in the coelenterate-platyhelminth line of evolution. It is more likely that both the turbellarian flatworms and the creeping ctenophores have evolved in a parallel fashion from different ancestors.

See COELENTERATA for more details on anatomy and physiology.

**COMBUSTION.** This term denotes the process of burning in the sense that a combustible substance is consumed by fire and flames. Theories on the nature of fire and flames have played a prominent role in the history of science. During the middle ages, the ancient notion that fire was an element universally prevailed until Francis Bacon classed it among his "phantoms of the market place" as one of these "fictions which spring from vain and false theories" (*Novum Organum*). About 1660 Robert Boyle, with the assistance of his pupil, Robert Hooke, proved with an air pump that neither charcoal nor sulfur burns when strongly heated in vessels exhausted of air, although each inflames as soon as air is readmitted. He also found that a mixture of either substance with saltpetre catches fire even when heated in a vacuum and concluded that combustion depends upon the action of something common to both air and saltpetre. To this was added the further discovery that in the calcination of metals a ponderable "fire-stuff" is taken up. Robert Hooke (*Micrographia*, 1665) stated that flame "is nothing else but a mixture of Air, and volatile sulphureous parts of dissoluble or combustible bodies, which are acting upon each other whilst they ascend. . . ." John Mayow, another of Boyle's pupils, experimented with candles and other combustibles burning in a bell jar of air enclosed over water. He observed that the air is diminished in bulk and that when the

### Evolutionary Relationships

—The relationship of the ctenophores to other animals has been the theme of much speculation. Formerly they were considered to be a class or subphylum of the phylum Coelenterata (or Cnidaria). Although some textbooks still maintain this classification, most of the more modern authorities separate Ctenophora as an independent phylum. The separation is based upon (1) the lack of the characteristic stinging cells (cnidoblasts, containing nematocysts) of the coelenterates; (2) the existence of a definite mesoderm in the ctenophores; and (3) the fundamental differences in the embryological development in the two phyla.

It is, however, generally conceded that ctenophores and coelenterates were derived from the same evolutionary stem. This is indicated by the primitive radial or biradial organization of the body in both groups, by the ex-

flame expires the residual air is inactive and will not support combustion. He also observed that the respiration of animals in an enclosed space had the same effect, and concluded that respiration and combustion are analogous processes. His views on the subject expounded in his *Tractatus Quinque Medico-Physici* (1674) are nearly correct, and but for his early death in 1679 he might have discovered oxygen.

However, the development of the phlogiston theory by G. E. Stahl at the beginning of the 18th century completely ignored the facts brought to light by Boyle and his students. In essence, the theory proposed that all combustible matter was composed of two principles, one called "phlogiston" (from the Greek, "burned"), which escaped during combustion, and the other, termed "calx," which remained as a residue. The phlogiston theory dominated chemical thinking for a time because it satisfied the need for a common, if wrong, explanation of a great number of otherwise disconnected phenomena; and the period of its existence may properly be regarded as the incubation period of modern chemistry. It came to an end when Joseph Priestley in 1774 (and, independently, K. W. Scheele in 1775) discovered the gas later named oxygen by A. L. Lavoisier. The latter in 1783 denied the existence of phlogiston and advanced instead the theory, amply supported by facts, that oxygen is the active constituent of the air, that it is necessary to the burning process and that it enters into chemical combination with the substance undergoing combustion.

Lavoisier's methods of quantitative experimentation and of scientific reasoning no less than his discoveries initiated the era of modern chemistry. After his time combustion ceased to be a problem of central interest to science, although much work continued to be done to elucidate the physical and chemical processes, or, as it may be called, the mechanism of combustion. Hydrogen burns to water, and certain other fuels burn to carbon dioxide and water; but in the transformation to these ultimate products many steps are involved.

**Combustion of Solid Fuels.**—In the combustion of wood and coal the first stage is the burning of volatile matter, usually in the form of sooty and turbulent diffusion flames (see *FLAME*). This volatile matter is formed by thermal decomposition of a part of the fuel substance and constitutes a complex mixture of gases and tar-forming vapours, such as is obtained in coal-distillation plants. The residual charcoal or coke burns without flame at the rate at which molecules of oxygen reach its surface, provided that a high temperature is maintained by the heat released in the chemical combination of oxygen and carbon. Various chars and cokes require quite different temperatures to maintain combustion, ranging from about 400° C. for reactive chars to about 800° C. for dense cokes. If the surface of a coke particle loses heat by radiation to some cold surface or open space, combustion stops; however, in the crevices of a fuel bed the radiant heat is absorbed and returned from other incandescent fuel particles, and combustion maintains itself.

When air passes through a coke or charcoal bed, combustion within the crevices is incomplete, the gaseous product being largely carbon monoxide, a dangerous poison. Normally, this gas meets sufficient air at the top of the fuel bed to burn completely to carbon dioxide, forming faint bluish flames. However, there are always chilling surfaces which permit traces of the gas to escape unburned; and when an open coal fire or an overrich gas flame burns in a poorly ventilated room, carbon monoxide accumulates in the air and becomes a serious hazard.

For smokeless combustion of coal in a furnace a moderate excess of air above the fuel bed is required. In addition to the air admitted from below an auxiliary air supply is admitted at the front or rear of the furnace. If a large amount of fresh coal is thrown on the fuel bed, an excess of volatile matter is formed; hence, it is necessary to supply the coal in small quantities at frequent intervals, or continually by a mechanical stoker. The soot-bearing combustion gases must not be prematurely chilled; hence, the furnace must be properly designed to maintain a high wall temperature of the combustion chamber and to allow thorough mixing of air and combustion gases.

Spontaneous combustion, or self-ignition, sometimes occurs

when combustible matter is stored in bulk. It begins with a slow oxidation process which, however, releases enough heat to raise the temperature perceptibly. As additional air seeps through the crevices, the temperature is gradually raised until inflammation occurs. Soft coal in small size tends to spontaneous combustion and must be wetted down.

Liquid fuels do not burn as such but only when they are volatilized and thus are miscible with oxygen or air in the vapour state.

**Combustion of Gases.**—Concerning the nature of the gaseous state, it is known that the molecules of a gas are in rapid motion, or "thermally agitated," and collide frequently with each other. Since at ordinary temperatures the fuel gases can be mixed with oxygen without inflaming or even oxidizing slowly, these molecular collisions *per se* are evidently entirely ineffective. At high temperatures, collisions involving high energy become more frequent, and this may lead to breakup and chemical combination of the colliding molecules. It was formerly thought that all molecules of oxygen and fuel gas reacted in this way, but with the development of chemical kinetics (see *REACTION KINETICS*) it became known that, at the temperatures of combustion, little direct reaction of this kind occurs. Instead, it has been reasonably well established that combustion occurs generally by reaction chains. For example, a high-energy collision breaks up a molecule into atoms or "free radicals" (*q.v.*); such a molecular fragment reacts with a molecule of fuel gas, which thereby becomes enabled to react with an oxygen molecule; in the latter process, an atom or free radical is again released, thus continuing the chain. Chains are broken when two atoms, or free radicals, combine to form a stable molecule, either in the gas space or, as happens most frequently, after first being adsorbed at a solid surface. Chain reactions may thus be suppressed by introducing fragments of broken glass and the like into the reaction space. Alternatively, the number and the length of the chains may be controlled by regulating the temperature of the reaction vessel and the density and composition of the mixture; or by controlling the rate of flow of a mixture through a heated tube. The term "slow combustion" refers to such controlled reactions. By means of slow combustion, intermediate oxidation products can be obtained; for example, aldehydes and organic peroxides from mixtures of hydrocarbons and oxygen, and hydrogen peroxide from hydrogen and oxygen. During slow combustion of paraffinic hydrocarbons (gasoline vapour, for example), a bluish glow is occasionally observed, which is termed "cool flame" and is caused by chemiluminescent formation of aldehydes.

**Explosive Combustion.**—If in the chain-continuing step more than one chain carrier is formed, as happens under certain specific conditions, the chain is branched; and if branching is not effectively checked by chain breaking, the combustion of the gas mixture in the reaction vessel becomes self-accelerating. Molecular events being extremely rapid, the combustion is completed in perhaps less than a thousandth of a second; this reaction may properly be termed an explosion and follows the principle of the atomic bomb explosion, where the chain carriers are neutrons and the chain is branched by the release of more than one neutron in the fission reaction of a neutron with the nucleus of a uranium or plutonium atom. However, the energy liberated in a fission reaction is incomparably larger than that in an ordinary chemical reaction. Another cause for explosion arises when the rate at which heat is released in the reaction exceeds the rate of heat dissipation. The temperature of the mixture rises, and the increase in temperature generally accelerates the combustion by shortening the duration of the chain cycles; this effect in turn accelerates the rise of temperature, and so on. Under some conditions explosions are purely of the latter type (thermal); under others they are of the branched-chain type and under still others they are of mixed thermal and branched-chain types. In any particular instance, the kind of explosion which occurs is determined by the nature of the gases, their proportions in the mixture and the imposed confinement, temperature and density.

The explosive reaction initiated by a critical combination of such conditions proceeds simultaneously in every part of the vessel. In contrast, a spark passed at some point of the vessel becomes surrounded by a narrow zone of intense combustion which

spreads as a wave from layer to layer of the gas mixture by heat transfer and diffusion of chain carriers. This process is also occasionally referred to as an explosion. (For combustion waves in gas streams, see *FLAME*.) Turbulent gas motion aids the heat transfer and thus accelerates progress of the combustion wave. In tubes the thermal expansion of the burning gas induces considerable flow with attendant pressure waves. With high-explosive mixtures these pressure waves and the combustion wave merge into a detonation wave, which constitutes a self-propelled shock wave traveling along the tube at a rate exceeding the velocity of sound in the burned gas.

*Knock in internal-combustion engines* of the four-stroke cycle type is sometimes referred to as detonation; however, it is not caused by the merging of combustion and pressure waves, but by a mixed thermal and branched-chain explosion occurring in the unburned gas ahead of the combustion wave. As the latter spreads from the spark plug through the cylinder head, the unburned gas in the rest of the chamber is compressed and heated; this produces an initially slow but self-accelerating combustion which, with low-octane motor fuels, becomes explosive before the combustion wave has completely overrun the gas mixture. It is conceivable that, under special conditions, the ignition of this end gas may start at a number of points simultaneously and even close to the oncoming combustion wave, and that this effect may result in a markedly accelerated combustion wave through the highly reacting and incipiently igniting gas. The explosion leads to violent gas vibrations which increase the heat flow to the engine cylinder wall—a dangerous condition for aircraft engines which, because of their size, cannot dissipate the excess heat. Tetraethyl lead destroys certain types of chain carriers and thus improves the knock resistance of motor fuels. The speed of the combustion wave is largely determined by the turbulence prevailing in the chamber. Without turbulence, it would be too slow, and the engine could not operate. (See also *INTERNAL-COMBUSTION ENGINE*.)

*Catalytic combustion* is exemplified by the reaction of hydrogen and oxygen on surfaces of platinum or palladium. Hydrogen molecules diffuse into the metal and dissociate into atoms there; they are thereby enabled to combine with adsorbed oxygen, ultimately forming water vapour. Finely divided metal (platinum sponge) can become so hot that the mixture is ignited. In compact form the metal remains comparatively cool and is thus generally non-incendive. For heats of combustion, see *HEAT*; see also references under "Combustion" in the Index volume.

**COMÉDIE FRANÇAISE.** The national theatre of France and the most famous of the European state-subsidized theatres, often also called the Théâtre Français or La Maison de Molière, was organized in 1680 by direct decree of Louis XIV issued in his military camp at Charleville. It was originally formed by joining Molière's troupe (amalgamated in 1673 with the Théâtre de Guénégaud, formerly the Théâtre du Marais) with the most ancient Paris company, the troupe of the Hôtel de Bourgogne.

The Hôtel de Bourgogne theatre was surrendered to the Comédie Italienne, and the united French company, called Comédie Française to distinguish it from the Italian troupe, performed at the Théâtre de Guénégaud until Jean Baptiste Lully (q.v.) succeeded in dispossessing them. They converted a tennis court (*le jeu de paume de l'Étoile*) in the Rue Neuve des Fossés, St. Germain-des-Prés, into a theatre, which they occupied from 1689 to 1770. Their theatre and location no longer suitable, they moved to the Salles des Machines at the Tuileries, where they remained until a new theatre (later called the Odéon) was erected for them and opened in 1789 in the garden of the Hôtel de Condé, near the Luxembourg palace on the left bank. The conflicts of the French Revolution caused a split in the company of the Comédie in 1791. The revolutionary liberals under the leadership of François Joseph Talma (q.v.) seceded from the more conservative group under François René Molé and moved to a new theatre in the Rue de Richelieu, then called the Variétés Amusantes. After the burning of the

older theatre on the left bank, the company was again reconstituted in 1799 and has continued since that date to make its home in the Rue de Richelieu. In 1816 Louis Benoît Picard, with a subvention, reconstituted the Théâtre Royal de l'Odéon on the left bank and established a company. The new Odéon, after again being destroyed by fire in 1818, was rebuilt with government aid and subsidized as the second-ranking theatre of Paris. On several occasions in the 19th century the two theatres were united under a single management. After the end of World War II, they were again united under one administrator and placed under the department of arts and letters in the ministry of education; both became branches of the Comédie Française with the two houses designated the Salle Richelieu and the Salle Luxembourg. In 1959 the Salle Luxembourg, renamed Théâtre de France, was again separated and the activities of the Comédie Française were confined to the Salle Richelieu.

The internal organization of the Comédie Française stems from the organization and operation established by Molière when his troupe returned to Paris in 1658. The company was organized as a co-operative society with the chief members, the *sociétaires*, having a direct voice in the operations of the organization, receiving a share of the net profits and being eligible for a pension upon retirement, usually after 20 years' service. The *pensionnaires* were actors hired at fixed salaries "on probation" and without the voting, profit-sharing and pension privileges; from the ranks of the *pensionnaires* new *sociétaires* were elected annually. Louis XIV perpetuated this organization and operation when he established the united company, and Napoleon in his famous Moscow decree, Oct. 15, 1812, substantially confirmed and reiterated the long-standing policy. Externally, as a state institution, Louis placed the theatre under the supervision of the gentlemen of the chamber. Around 1756 this function was taken over by the *intendant des menus* and in 1799 the theatre was placed under the jurisdiction of the department of the interior. The external management changed during the 19th century with the fall and rise of French governments, and various acts and decrees altered and curtailed the powers and duties of the *sociétaires*. With the reorganization after World War II, the administrative head of the Comédie is nominated by the director-general of arts and letters and appointed by the minister of education.

During the period of its monopoly, prior to the decree of 1791 on the liberty of the theatres, the Comédie was the only Paris theatre in which new plays could be produced. After that decree, and especially during the 19th century, it tended more and more to build its repertory from the great masterpieces of French drama of the past, though it never abandoned entirely the production of new scripts and modern plays. In 1900 it gave 267 performances of older classical plays and 419 performances of contemporary pieces; in 1952, by contrast, it presented 567 performances of classic plays and 456 of contemporary. It has produced the plays of all of the great French dramatists and the most eminent actors in the history of the nation have appeared upon its boards. Its fame rests upon an illustrious history, upon the splendid ensemble performances of its actors and upon its conservation and perpetuation of the best in the French theatre and drama. It is cherished by the French people as a national theatre and as a cultural and educational institution.

**COMEDY** is a term used of both dramatic and nondramatic literature. As used in the 20th century to describe contemporary drama, it applies to plays written in a light and humorous style, with laughable incidents and characters. This usage, however, is inadequate to cover what has been and still is recognized as comedy in the drama of the past. Comedy for the Greeks was a definite genre which seems to have developed out of rites and celebrations involving song and the wearing of masks. The fact that there was an element of fertility ritual in these origins has led some authorities to accept the tradition that the actors of comedy wore the leather phallus; but other modern experts do not believe

that this actually happened in performance. It is agreed, however, that the earliest forms of Greek comedy apparently developed as a combination of ritual chorus with histrionic episodes. Aristotle says in his *Poetics* that plot and unifying theme were first introduced by Crates. Comedy was first performed as part of the competitive city festival in Athens in 486 B.C. It is usual to talk of three phases of Greek comedy proper, the earliest, Old Comedy, retaining chorus, mime and burlesque from the older forms. Old Comedy, of which the most famous exponent—and the only one whose work has survived—was Aristophanes, included fantasy in its exuberant and high-spirited satire of public persons and affairs. As it was not restricted completely to political satire, it has been suggested that Old Comedy developed quite naturally into what is called Middle Comedy, the preoccupation of which with social themes should not be regarded as a new departure in a new form. (No plays of Middle Comedy are extant.) This phase was followed by that of New Comedy, introduced by Menander (q.v.), which deals with contemporary manners and with familiar and domestic themes, with plots composed of intrigue and involving romance (see also DRAMA: *Greek Drama; Roman Drama*).

The attitude to humanity and affairs expressed in such art is obviously different from that involved in the expression of heroic themes in tragedy and epic. Aristotle was describing what existed as much as dogmatizing about what ought to exist when he stated that instead of expressing the heroic conception of life, comedy essentially dealt in an amusing way with plebeian characters in everyday situations. It followed that a high and heroic style of writing could not be used to express what had not been conceived in a heroic spirit. These were the fundamental assumptions about persons, attitudes, themes and style which the Romans took over from the Greeks, together with the masks, stock characters and love intrigue of New Comedy. Roman comedy, however, involved more sheer enjoyment; it has been described as amusing, reflective and, in some cases, moral. As satire of public men was too dangerous, ordinary people became the target and social and religious matters were not exempt. In the typical plot a young gentleman in love with a slave girl tries to raise money to buy her; eventually she is revealed as a long-lost child of a family of rank equal to his, who has preserved herself chaste; and so they can be married. From Roman comedy, as written by Plautus and Terence (qq.v.), postclassical critics developed a conception of comedy as a play of quality, of good literary style, capable of inspiring morality as well as mirth. The later form, the *fabula togata*, treated of rural and small town society and contributed to the methodical development of a dogma that comedy's function was to teach and delight by exhibiting a picture of ordinary unheroic persons and events in a suitably low or mediocre style of writing. Cicero described it as "the imitation of life, the glass of custom and the image of truth." Traditionally, moreover, its events involved no serious dangers. These ideas combined to inspire the definition, ascribed to the 4th-century Donatus (q.v.), that comedy is concerned with private affairs, without violence or danger to life, with unhappiness giving way to a happy outcome in which lost children are recognized and from which men may learn what is useful and what is to be avoided.

The fact that comedy was drama was probably never forgotten completely, but in the early medieval period the term was extended to types of nondramatic literature possessing some of the essential qualities of the dramatic genre. For the Spanish encyclopaedist Isidore of Seville (c. 560–636) the genre encompassed Old Comedy, consisting of the plays of Plautus and Terence, and New Comedy, which was undramatic and was composed of the satires of Horace, Persius and Juvenal. Eventually, narrative with a happy ending in a familiar style of elegiac verse was described as comedy; and by the 12th century the term applied to versified narrative. For many, comedy was a poem beginning in sadness and ending in joy; and Dante called his *Paradiso* a comedy partly for this reason and partly because it was written in the "speech for the masses in which even womenfolk converse" and not in heroic Latin verse.

In the Renaissance critics had classical authority for the two dominant conceptions of comedy, which was now a strictly dra-

matic form again. The first type, associated with Ben Jonson (q.v.) in England, is in the tradition of Aristophanic satire, exposing the ridiculous sins of the petty to the punishment of well-deserved derision. This form owes much to the apparent authority of Cicero and the medieval grammarians for the assumption that comedy is critical and realistic in its treatment of the life of ordinary unheroic people, being in Jonson's words, "a thing throughout pleasant and ridiculous and accommodated to the correction of manners." Low style and intricacy of plot was shared by this kind of comedy with the other, which, in the words of Thomas Heywood (q.v.), begins "in trouble" and ends "in peace." Each of these kinds of Renaissance comedy avoids the heroic in style, person, incident and theme; and each comes nearer to the realistic in its treatment of its subject, especially in characterization which tends away from the ideal to the individual. To some extent *A Midsummer Night's Dream* has the qualities of the second kind, its intrigue ending in the triumph of true love, passing from unhappiness to joy; but it is quite different in the qualities which make it representative of popular English comedy, for it mingles high and low persons and styles; it involves the heroic as well as the ridiculous and the plot does not avoid danger. English popular comedy, happy in its outcome, can nevertheless include danger and bloodshed. It should not, however, be confused with a strict neoclassical relation, tragicomedy, as practised by Guarini in *Il Pastor fido* (1590) and defined and defended theoretically as a not unclassical compound of fused elements from classical tragedy and comedy, mingling the heroic with the unheroic in style, person and incident, avoiding tragic catastrophe for a happy outcome in which punishment by death or derision gives way to reconciliation. The romantic comedy of Beaumont and Fletcher (q.v.) and Shakespeare's *Measure for Measure* and his last four comedies are fundamentally akin to this neoclassical form in their fusion or attempted fusion of the tragic and comic spirits without doing violence to either. Another form of comedy in many ways similar was that of 17th-century Spain, which did not aim at laughter but avoided bloodshed, giving a happy ending to intrigues of love and considering, if superficially, the serious issues of conduct, love and honour which led to misery and bloodshed in tragedy. In France and England the same century saw more attention given to laughter and the correction of follies embodied in individual characters. Not only Thomas Shadwell, Jonson's avowed disciple, but the courtly Restoration dramatists of England treated character in their comedy of manners. In France, Molière treated similar themes and persons, but with more humour and less satirical bite. For him the function of comedy was "to enter rightly into the ridiculous aspects of mankind and to represent people's defects agreeably on the stage." French comedy, before him, had been derived largely from that of the Italians and Spaniards, but he makes his native, despite borrowings, and has a wide range of subjects and themes, treating avarice, jealousy, snobbery, both social and intellectual, but not love as such in a romantic way. He treats the particular and individual with an awareness of the universal, a task more difficult in comedy than in tragedy.

With the 18th century a new element entered into comedy in Europe, that of sentiment. The concentration was now on the story involving unhappiness and virtue beset with troubles which ended happily and which was still not conceived of in a high heroic style but dealt with events and persons in the circumstances of ordinary life. With much less wit and bite than the comedy of manners of the previous century, this comedy of sentiment in England dealt with characters not acting under the predominance of natural feeling, but warped from their genuine bent by the habits, rules and ceremonies of a sophisticated but not heroic high society. The equivalent of what was called "genteel comedy" in England is found in France and in Germany in the plays of such writers as Marivaux and Lessing (qq.v.). Where the sentiment degenerated into sentimentality the result was really something approaching melodrama, but avoiding the emotional excitement which is the melodramatic equivalent of tragic tension. The sentimental comedy of England had its counterpart in what was called the *comédie larmoyante* ("sentimental comedy") first made the

vogue by La Chaussée in France: in both, a true comic attitude of any kind is constantly menaced by the superficial exploitation of virtue to produce tears followed by the relief of experiencing the reward of a happy ending.

As comedy has always had a tendency to reject idealization in favour of what seems more real by the standards of everyday life, it was natural that in the 19th century the form responded quickly to the general pressure of naturalism on the arts as a whole, to the growing insistence upon the importance of the individual in scientific, social, political and philosophic thinking and to the gradual disappearance in society and thought of the heroic as conceived in former ages of aristocratic dominance. The form traditionally used to ridicule those who transgressed against accepted conventions and ideas was now employed to attack what had formerly been accepted, when it conflicted with, or ignored, the teachings of the new age. The fundamental ideas of the past were now treated in the spirit of ridicule which had once been turned upon old-fashioned garments, taste and ways of conducting oneself in society. This method was adopted by Dumas  *fils* in his comedies of social purpose and by Bernard Shaw in his comedies of ideas. Shaw in particular delighted in exposing the ridiculous element in outworn conventions as shown in relation to a modern world and with such subtlety and exuberance that his audiences found themselves laughing if protestingly. Toward the end of the century it was not unnatural that as the inevitability of change became apparent in Russia, the effect upon the society which recognized it as both welcome and unwelcome should have inspired the particular blend of irony and sentiment of Chekhov's comedy. Exhibiting a realistic picture of an existing society he is both sympathetically understanding of its inability to free itself from the elements of decadence within it, and ironically amused by the essential inadequacy of that society to cope with new times.

From Greek Old Comedy onward fantasy has been associated with the form, particularly when burlesque is present. Fantasy allows the dramatist especially to express his sense of the irrationality of the world, as one which might be regarded as a burlesque of itself. This attitude permeates plays like Johann Ludwig Tieck's *Der gestiefelte Kater* ("Puss in Boots," 1797) and the modern comedy of Eugène Ionesco, with its exposure of the real incoherence and breakdown of what is accepted at its face value by the world as rational communication with one another of members of a society of human and therefore rational beings. As the triumph of naturalism at the end of the 19th century seemed to be taking from the theatre those elements conventionally regarded as "poetic" to serve the needs of drama with a serious purpose, writers of comedy to some extent resorted to fantasy in order to prevent the drama becoming completely drab. The kind of comedy that results is seen in both J. M. Synge (*q.v.*) and Christopher Fry, with the latter grappling with the convention of realistic dialogue while writing verse.

The history of comedy shows it to be a form of drama whose complexity cannot be adequately dealt with by any definition which sees it as aiming simply at exciting laughter. Nevertheless, laughter is undoubtedly associated with comedy, a fact which has led to the discussion of the two together, notably by Henri Bergson, *Le Rire* (1900; Eng. trans., *Laughter*, 1911), J. Sully, *An Essay on Laughter* (1902) and George Meredith, *The Idea of Comedy* (1877). Meredith's thesis that comedy appeals to the intellect and not to the emotions and concerns the social group has rightly been rejected as too narrow. Consideration of comedies as they actually exist suggests that what might be regarded as different kinds derive fundamentally from differences in the attitude of authors toward their subjects, and their intentions with these respectively. When, for whatever purpose, the intention is to ridicule, satirical comedy emerges; when ridicule is turned on persons, the result is the comedy of character; satire of social convention and within social convention gives comedy of manners; social comedy concerns the structure of society itself; and satire of conventional thinking produces comedy of ideas. Progress from troubles to the triumph of love in a happy outcome produces romantic comedy; and Shakespeare's individual brand of this is suffused with a mellow humour rather than wit. The comedy of

intrigue derives from a dominant intention of providing amusement and excitement with an intricate plot of reversals with artificial, contrived situations. Such is the comedy of Spain in Lope de Vega, Tirso de Molina and their fellows. Where the author wants to exploit potentially serious issues merely sentimentally, never really approaching anything like the true emotion of tragedy, sentimental comedy results. Of course these kinds are not mutually exclusive; elements of one or more may appear in any.

It has often been observed that comedy flourishes in urban societies, with an established theatre and an agreed attitude toward conventions of conduct. The civilization must be sophisticated enough to allow more reliance to be placed on verbal than on physical comedy. For comedy is essentially a literary form and differs from farce in that the latter, which has been well described as exaggerated comedy, keeps character and dialogue dependent upon crude incongruities and contrived situations, seeking merely to provoke laughter. Nevertheless farcical elements exist in comedy, especially that of the Greeks and Romans. See also references under "Comedy" in the Index volume.

**COMENIUS, JOHANN AMOS** (JAN AMOS KOMENSKÝ) (1592-1670), educational reformer, theologian and last bishop of the Moravian Church, was born in eastern Moravia but spent much of his wandering life in religious exile, victim of the Thirty Years' War. His philosophy encompasses three levels: (1) Peace on earth exists only when religious factions cease fighting and unite toward realizing God's will. (2) Such understanding and co-operation can best be achieved through "pansophia," universal education and knowledge among all men and all nations by means of (3) widespread educational reforms in methods and principles of teaching, including a universal language, universal coeducation and a "college of light," a centralized pooling of all learning. Comenius regarded science as religion's handmaiden, not competitor. His *Gate of Languages Unlocked* (1631) revolutionized Latin teaching and was translated into 16 languages. *The Visible World in Pictures* (1658), which was popular in Europe for two centuries, attempted to dramatize Latin through pictures illustrating Latin sentences, accompanied by one or two vernacular translations. *The Labyrinth of the World* (1631), analogous to Bunyan's *Pilgrim's Progress*, was a major source of spiritual consolation to the exiled Moravians. Several of Comenius' pansophical works were published in England by Samuel Hartlib (*q.v.*), who persuaded him to continue writing in England and attempt to establish a pansophical college, with the co-operation of Hartlib's influential group of educators, theologians and scientists. Political turmoil cut short Comenius' stay (1641-42), but his presence initiated discussions that led to the founding of the Royal society (inc. 1662), to which he dedicated an important pansophic work, *The Way of Light*. The German philosopher Leibniz, influenced by Comenius, founded the Berlin Royal society, and similar societies appeared elsewhere.

When John Winthrop, Jr., traveled to Europe to invite some outstanding educator-theologian to become president of Harvard college, he visited Comenius (1642), and he may have asked Comenius to fill this office. New England clergymen were interested in Comenius' views on church discipline and on educating and converting American Indians.

The Swedish government, hoping to promote a national system of education, invited Comenius (1642) to reform the country's schools. His projects there included a series of graded Latin textbooks, widely acclaimed throughout Europe. His activity in several ecumenical conferences irritated Lutheran Sweden, however, and he was obliged to return to his church duties in Poland, where he was consecrated presiding bishop of the Moravians (1648), the last of the Bohemian-Moravian clergy to hold this office.

Invited to Hungary, Comenius established a pansophic school, which he hoped would be a model for a reformed educational system. But personality conflicts and numerous disputes dissipated

his energies and prevented broader adoption of his ideas. His activities became politically oriented in later years, and his thinking and efficacy suffered. Several of Comenius' 200 works, including those mentioned above, are available in English translation. See also CZECHOSLOVAK LITERATURE; MORAVIAN CHURCH.

**COMET.** A comet is a heavenly body revolving around the sun and consisting of a nucleus, a diffuse envelope or coma and, when close to the sun, a tail that may extend to great length. Minor members of the solar system include the comets, the minor planets (or asteroids), swarms of meteoroids and the multiplicity of finely divided particles that cause the zodiacal light and Gegenschein. Comets usually are distinguished from other members of the solar system by their more or less diffuse appearance and by the character of their orbits, but cases are known in which the distinction between comet and minor planet, for example, is not definite. There is increasing evidence that comets are the parents of meteor swarms and perhaps of all meteors, and the particles of the zodiacal light may also be largely of cometary origin.

Most comets move in very elongated orbits that differ little from parabolas and require thousands of years for completion. Some, in fact, appear to leave the solar system forever because of changes produced in their orbits by the gravitational attractions of the major planets. Other comets have orbits that resemble so closely those of some minor planets that distinction cannot be made between these bodies on the basis of orbital characteristics.

This article is divided into the following sections:

## I. INTRODUCTION

The name comet is derived through the Latin from the Greek word for "hair." It suggests an imagined resemblance between the tail of a comet and long hair streaming in the wind. The term used in China and in Japan, translated "besom (broom) star," may originate either from a comparison between a comet's tail and the bundle of twigs in a broom, or from the sweeping motion of a broom over a floor suggested by the motion of a comet's tail across the constellations.

**1. Nomenclature.**—Comets may be designated in three ways. The first is by the year of discovery followed by a small letter (in italics) indicating the order of discovery or recovery in the year (e.g., comets 1910a, 1927f, 1948f, 1953f). The second is by the year followed by a Roman numeral indicating the order in that year in which the comet passed perihelion, the point in its path closest to the sun (e.g., comets 1910 I, 1925 II, 1948 XI, 1954 IX). A comet might be discovered in one year and pass perihelion one or two years before or after discovery, and hence correctly be given two different year designations. Actually, as fainter and more distant comets are discovered through the use of increasingly powerful wide-field telescopes, discovery and perihelion passage take place in different years fairly often. The second designation supersedes the first when accurate orbital elements have been derived and sufficient time has elapsed to ensure that new dis-

coveries will not upset the order of perihelion passage determined within the year. The third designation is by the name or names of the discoverers of a comet or, less frequently, by the name of a person who has done extensive work on its orbit. Frequently the name is given in conjunction with one of the first two designations (e.g., Comet Latyshev-Wild-Burnham, 1957f) but, especially for some of the well-known comets that are observed at repeated perihelion passages (e.g., Halley's comet, Encke's comet), the name alone is usually used.

**2. Distances and Periods of Comets.**—Distances of comets from the sun vary within extremely wide limits; the comets 1880 I and 1843 I approached within 120,000 km. of the sun's surface, and several other comets approached almost as closely. There appears to be a great reservoir of comets, belonging to the solar system, at distances that are a large fraction of the distance from the sun to the nearest star (40,000,000,000,000 km.). Periods required by comets to complete a single revolution in their orbits also vary enormously. The shortest verified period is that of Encke's comet,  $3\frac{1}{2}$  years. The longest computed periods have little real meaning, for comets moving in very large orbits can be observed over so small a fraction of the total path that the value found for the period has little significance. But periods certainly amount to millions of years for some observed comets.

**3. Comets in Ancient Times.**—Comets appear at irregular intervals and their rapid and often unpredicted movements, combined with the occasional enormous length and brilliance of their tails, have caused them to be regarded with mingled interest and apprehension. Since the belief was long prevalent that the movements of the heavenly bodies influenced the affairs of men, it is natural that comets were once regarded with considerable suspicion and interest. Later they were associated with plague, famine and war. These ideas had the useful result of causing the movements of comets to be noted with great care. Many such records have come down to us, especially in the Chinese annals; they have been useful in tracing the history of Halley's comet back at least to 240 B.C. and in providing probable identification of a few other comets.

In early times there were two schools of thought concerning the nature of comets: one regarded them as true celestial bodies, the other as vaporous exhalations within the earth's atmosphere. The former view was held by the Roman philosopher Seneca, who made the forecast: "Some day there will arise a man who will demonstrate in what regions of the heavens the comets take their way; why they journey so far apart from the other planets; what their size, their nature." Unfortunately, European astronomers for many centuries exhibited less sagacity than Seneca and adopted the view that comets were atmospheric exhalations, though this idea could have been easily refuted by the fact that comets share in the daily revolution of the heavens, rising and setting like the stars. The erroneous view had the effect of causing very little attention to be paid to the positions of comets among the stars, so that up to the 16th century European cometary records are far inferior in accuracy to those of the Chinese. One of the useful achievements of Tycho Brahe (1546-1601) was to establish, by comparison of observations made at two widely separated observatories, that comets are more remote than the moon and therefore must be regarded as heavenly bodies.

## II. THE PHYSICAL NATURE OF COMETS

In predicting the motion of comets, the assumption is made that the only force acting is the gravitational attraction of the sun and planets. The assumption is fully justified by the fact that in all cases in which previous appearances of a comet have been well observed, and in which the perturbations have been carefully computed, the observed position has been exceedingly close to that predicted. It is quite clear, however, that material in the coma and in the tails of comets is acted upon by a repulsive force, originating in the sun, which is in many cases much stronger than the gravitational attraction. It is concluded that the material in the coma and especially in the tail is in a much more finely divided state than that found in the nucleus.

**1. The Nucleus.**—Several lines of evidence indicate that the nucleus is composed of one or a very few solid blocks of the order

of one kilometre in diameter. The fact that the repulsive forces are negligible, in comparison with the gravitational attraction of the sun, in governing the motion of the comet as a whole indicates that the nucleus contains lumps of moderate size. The ability of the nucleus to survive the effects of intense solar radiation during the extremely close approaches to the sun experienced by some comets also speaks for bodies of significant size in the nuclear region. The regularity with which some comets emit halos and the presence of effects that may be caused by rotation of a single nuclear body also argue in this direction. A few comets, *e.g.*, Comet Pons-Winnecke in 1927 and Comet Schwassmann-Wachmann 3 in 1930, have approached the earth so closely that measures of the size of the nucleus could be made directly. On those occasions F. Baldet, V. M. Slipher and others found diameters of the nuclei of about half a kilometre. At the same time, there are facts that argue against much larger nuclear bodies. In the instances in which comets have transited the sun, no body has ever been seen silhouetted against the sun's disk. The total mass of a comet is exceedingly small, and no case is known in which a comet has produced an observable perturbation in the motion of another body.

Lexell's comet of 1770 and Comet Brooks 2 in 1886 passed through the satellite system of Jupiter with severe disturbances to the cometary orbits but without producing any observable effect on the motions of any of the satellites.

The gases evaporated, sublimated or released by explosion from the nuclear body carry with them solid particles, and the nucleus is undoubtedly surrounded by a cloud of meteoric fragments and dust, as well as by the molecules of gas and the very small particles that form the coma and tail. The mass of the nucleus of a comet is quite insufficient to retain particles that become detached from the nuclear body, and such particles pursue independent orbits around the sun. Each trip to the vicinity of the sun costs the comet a permanent loss of material, and the loss cannot be made up by accretion of material in the outer parts of the solar system. The lifetime of a comet is limited, therefore, and the comets that are now being observed cannot have been long-time members of the inner solar system. Comets evidently vary a great deal in the amount of material contained and in the ability of that material to withstand the stresses of a close approach to the sun. To an observer comets show a good deal of variation in the degree of central condensation, but in only the most exceptional cases can the nucleus itself be observed directly.

Double and multiple nuclei are not uncommon but usually are very unequal in size and brightness, and the smaller fragments are quite short lived. Cases are on record, however, in which secondary nuclei have survived for many months or years, an example being Wirtanen's comet in 1957-59. Only very rarely are the nuclei of nearly equal size; the most remarkable example of disruption of this type was that of Comet Biela in the winter of 1845-46. This comet had been observed as early as 1772 and had eventually been recognized as periodic, returning every 6½ years. Nothing unusual had been noted until the comet was found to have split into two comets shortly after recovery in 1845. The two distinct comets traveled side by side and returned together, but more widely separated, in 1852. The position in the sky was not favourable in 1859, and neither of the two comets that had been seen in 1852 was observed. The circumstances of the return in 1866 were more favourable but, in spite of careful search, no sign of a comet was found then or subsequently. Fragments remained, however, and the presence of the original comet has been manifested in the form of showers of meteors; displays caused by swarms of meteoroids moving in the orbit of the comet occurred on Nov. 27, 1872, and again in Nov. 1885, 1892 and 1898.

Various other showers of meteors have been associated with known comets, examples being the Draconid showers of Oct. 9, 1933 and 1946, with Comet Giacobini-Zinner, and the Ursids of Dec. 22, 1945 and 1946, with Tuttle's comet. Some showers that recur every year also have been associated with known comets; *e.g.*, the May Aquarids and October Orionids with Halley's comet, the Perseids of August with Comet 1862 III and the Leonids of November with Comet 1866 I. Complete disruption of the parent

comet is by no means a necessity for the presence of an associated meteor swarm.

Studies of the behaviour of meteoric particles during their flight through the earth's atmosphere have shed direct light on the character of the material in individual comets and have revealed significant differences from comet to comet in the tensile strength and composition of the material. The material is all very fragile, with densities, according to F. L. Whipple, roughly 0.1 that of water. Evidence is accumulating that nearly all sporadic meteors may also derive from comets. Studies of meteors may be expected to be very instructive as regards the composition of comets; perhaps ultimately it may be possible to determine the place and mode of comet formation.

The frequency with which comets disintegrate also suggests material of very low strength. Some comets have literally gone to pieces and become very faint diffuse clouds without central condensation, or have even disappeared, without apparent cause. Comet Enser became very diffuse and faint in 1926, and Comet Pajdusakova disappeared in Dec. 1953 instead of becoming an object as bright as Sirius, as had been expected for Jan. 1954. Some other comets have been even slightly diffuse in aspect on only very rare occasions, normally being indistinguishable in appearance from minor planets. Comet Neujmin 1 (1913 III) is of this latter type; a trace of coma was evident on only one or two occasions. One indeed is inspired to wonder whether some minor planets may not be cometary in origin, being the remnant left when the volatile materials of a cometary nucleus were exhausted.

**2. The Coma.**—The coma is the diffuse envelope formed by the gases and dust driven out of the nucleus by solar radiation. It is an impermanent feature without definite boundary and is frequently present even when comets are observed at very great distances from the sun. The material involved is constantly replenished from the nucleus and is eventually lost to the comet because the gravitational attraction of the small central mass is quite negligible compared with the disrupting forces. When velocities of material in the coma have been measured they have been found to be 0.1 to 2-3 km. per second. The motions are generally directed outward from the nucleus in the inner part of the coma, but are modified in the outer coma by radiation pressure.

The diameter of the coma cannot be precisely defined, partly because of the hazy boundary and partly because the apparent diameter is intrinsically different in light of different colours. Molecules of gas escaping into the coma from the nucleus are broken down from polyatomic "mother molecules" into a succession of simpler compounds. Each molecule radiates in certain characteristic wave lengths of light, and the apparent diameter of the coma measured in the light of a particular colour depends on how rapidly molecules of a given species are broken down by the solar radiation into a state in which they no longer emit light of that colour. The visual diameter of the coma is determined principally by the light of C<sub>2</sub> and is smaller than the photographic diameter, which is essentially that resulting from CN. While a comet is approaching the sun, the coma normally increases in diameter as more gases are released from the nucleus, but the increasing radiation incident on the comet also breaks apart the radiating molecules more rapidly. When the comet approaches the sun closer than about 1.4 A.U. (the astronomical unit, the mean distance of the earth from the sun, is about 93,000,000 mi. or 150,000,000 km.), the coma begins to shrink again. It is nearly always larger than the earth and often is much larger. The coma of Halley's comet in 1910 reached radii up to 200,000 km.

The nucleus and coma together are called the head of the comet. Sometimes structure may be seen in the head, usually in the form of "fountains" or "jets" which occur when dust and gases are ejected from a particular part of the nucleus, or as "hoods," which are produced when the ejection is more symmetrical around the nucleus but takes place unevenly in time.

**3. The Tail.**—The tail of the comet is formed of molecules and very finely divided dust particles driven out from the coma by the pressure of radiation from the sun. The true tail, which always extends more or less away from the sun, may reach enormous

### SOME REPRESENTATIVE COMETS

1. Halley's comet, May 4, 1910. Halley, in 1704, was the first astronomer to establish the fact of a comet's periodic return and to calculate its elliptical orbit. His calculations were verified by the reappearance of the comet in the years 1759, 1835 and 1910, as well as by tracing the history of previous appearances back to 240 B.C.
2. Comet Morehouse, 1908 III, photographed on three successive nights, 1908, Sept. 30, Oct. 1 and Oct. 2, by E. E. Barnard. These pictures illustrate how the tail material moves rapidly away from the comet's head, sometimes producing the rapid changes shown. The speed of recession of features in the tail sometimes reaches 100 km. per second.
3. Comet Pons-Winnecke, June 23, 1927. This is a member of the Jupiter family of comets named after Jean Louis Pons who discovered it in 1819 and Friedrich Winnecke who rediscovered it in 1858. The photograph shows this relatively faint comet at a distance of only 4,000,000 miles from the earth. Stars are visible through the transparent cometary envelope (coma). This comet's orbit is changed by perturbations every alternate revolution. The photograph illustrates the general appearance of all comets when at a great distance from the sun.
4. Comet 1941c as photographed on Feb. 15, 1941, by Dr. G. Van Biesbroeck with the 24-in. reflector of the Yerkes observatory. This comet was discovered by R. P. de Kock of Paarl, South Africa, on Jan. 15, 1941, but first announced to the world in general on

Jan. 23, 1941, by Dr. J. S. Paraskevopoulos of the Boyden station of the Harvard observatory in South Africa. It attained its closest approach to the sun on Jan. 27, 1941. It became brighter than the third magnitude and observers of the southern hemisphere saw it as a bright naked-eye object. In the photograph the head is overexposed to bring out structure in the tail, so the bright pointlike nucleus in the head is lost in the photographic process.

- 5, 6 and 7. Photographs, with the spectrograph, of Comets Peltier (1936a), Whipple-Fedtko-Tevzadze (1942g), and Cunningham (1940c), respectively. These illustrate the differences in cometary spectra. Comet Peltier showed an almost pure solar-type spectrum, the only characteristic cometary band being an extremely faint one due to CN. Comet Whipple-Fedtko-Tevzadze exhibits fairly strong emissions due to CN, C<sub>3</sub>, C<sub>2</sub>, etc., superposed on a solar type reflection spectra. For Comet Cunningham, the cometary emissions were very much more intense than the solar-type spectra. In (5) and (6) iron arc comparison spectra are shown above and below the comet's spectrum. No comparison spectrum is shown in (7). (5) and (6) cover the ordinary photographic region, from the blue-green down to the far violet. (7), taken with an ultra-violet spectrograph, covers the region from the red far into the astronomical ultra-violet. It shows the recently discovered OH and NH bands in the ultra-violet. Emission bands due to the various compounds are indicated

Comet Mrkos, showing the structure of the head and inner tail, Sept. 15, 1957. This photograph, made with the 40-in. reflector of the U.S. Naval observatory, Flagstaff, Ariz., is on a very much larger scale than that of the photographs of Mrkos below and shows only a small portion of the tail

Periodic Comet Arend-Rigaux, Feb. 16, 1958. This comet, like a few others, has been entirely sharp in appearance on some occasions, with no trace of coma or tail. At such times a comet cannot be distinguished from a minor planet, or "asteroid," by appearance alone. Photograph made by 40-in. reflector

Periodic Comet Encke, Sept. 19, 1957, just before its 45th observed perihelion passage. This comet was the second for which an elliptic orbit was calculated and a return predicted. The very asymmetrical location of the nucleus in the coma may lead to systematic errors in the observed position of this comet

Comet Mrkos, photographed with the 48-in. Schmidt telescope, Palomar observatory, Calif., Aug. 22, 24, 26 and 27, 1957. Comets with two or more tails are not uncommon, but rarely are their tails so well photographed. The straight tail with prominent streamers and irregularities is formed of ionized molecules, while the more uniform, curved tail is composed primarily of small, solid particles

Comet Arend-Roland, also photographed with the Palomar 48-in. Schmidt telescope, April 26, 27, 29 and 30, 1957. The thin "spike" opposite the normal tail was caused by an edgewise view of particles scattered in a plane of the comet's orbit through which the earth passed

Comet Wirtanen showing the double nucleus and a faint tail. The two nuclei were first noticed May 1, 1957, and persisted until the comet became too faint for further observation late in 1959

## RECENTLY OBSERVED COMETS

lengths. The tail of Halley's comet in 1910 reached a length of 30,000,000 km., and tails as long as the distance between the earth and the sun have been observed. The tail may be nearly straight and pointed almost directly away from the sun, or it may be moderately or highly curved and form a large angle with the antisolar direction. Comets not infrequently have at the same time several tails of differing curvatures. When the comet of 1774 had six divergent tails, this phenomenon was looked on as very abnormal, but photographs in modern times have shown that multiple tails are quite common.

The curvature of the tail is indicative of the strength of the repulsive force driving material outward from the coma. Measurements of the motion of identifiable irregularities in the tails of various comets have demonstrated the presence of repelling forces from a few times to more than 2,000 times stronger than the sun's gravitational attraction. In the interpretation of the measurements, the assumption has almost always been made that the tail lies in the plane of the orbit of the comet, but this assumption may not be valid if significant velocities of ejection of material from the nucleus are present. It is not known whether such ejection effects are important.

The weaker repelling force has been identified with the pressure of solar radiation. This pressure is effective only on particles of very small size. Large accelerations cannot be produced by radiation pressure, and a good deal of evidence exists to support the probability that electrical and perhaps magnetic forces play an important role.

Detailed study of the structure of comet tails began with F. W. Bessel's investigation of the tail of Comet 1835 III. Since Bessel's time many astronomers have attacked the problem, but knowledge of the structure and composition of the tails of comets is still very primitive.

F. A. Bredichin classified tails into three types depending on the degree of curvature. Straight tails are bluer in colour than the more highly curved ones. They therefore are often of striking prominence on ordinary photographs made in blue light, although visually they are not conspicuous. On the other hand, photographs rarely show more detail in the curved tails than can be seen visually. Straight tails often show much structure in the form of streamers and very irregular distribution of material in knots and clouds. Very profound changes in appearance may occur within a few hours. The extremely active tail of Comet Morehouse (1908 III) was of the straight type; photographs of it are found in practically every publication that mentions comets. Curved tails also may show interesting structure, but such structure is generally confined to a system of rays or streamers. These may be quite narrow and often appear to diverge in the shape of the ribs of a fan; they often have a slight curvature, sometimes concave and sometimes convex to the axis of the tail. The differences in colour and curvature of tails suggested the possibility of differences in composition, but convincing spectroscopic data supporting this view was not obtained until 1957. The more highly curved tails were theorized to be composed generally of neutral molecules and dust, which would be repelled by relatively weak pressure of solar radiation. Straight tails were known usually to be composed of ionized molecules, and it was suggested that high accelerations might be produced by friction between the molecules and the electrically charged particles of solar corpuscular streams. The corpuscular streams, which contain both protons and electrons, are identical with the particle streams associated with geomagnetic storms and the polar auroras. They are directional, vary greatly in intensity and travel with velocities of 100 to 1,000 km. per second. Rapid changes in tail structure might be caused by such ion streams. Furthermore, several comets visible at the same time in different parts of the sky might be affected differently by the corpuscular streams and show vast differences in activity.

Comet Arend-Roland (1956h) for a few days late in April 1957 possessed a most remarkable spike or anomalous tail extending in a direction almost exactly opposite to a second tail, a long normal one of moderate curvature. The direction of the spike with respect to the normal tail changed noticeably from night to night, and it was recognized promptly that the appendage was not a true

tail but an edgewise view of debris scattered along the orbit ahead of the comet. The spike was visible only for a few days as the earth passed through the plane of the comet orbit. The spectrum of the spike was predominantly of the solar type, indicating the presence of dust and larger molecules rather than the ionized radicals of the normal tail. During Aug. 1957 Comet Mrkos (1957d) showed at the same time a very active straight tail and a strongly curved quiescent tail, with the sector between the two tails filled by a very intricate system of narrow rays. The straight tail showed the usual comet-tail spectrum produced by ionized radicals. The curved tail showed principally the solar-type spectrum produced by sunlight reflected and scattered by dust and large molecules.

**4. Spectroscopic Observations of Comets.**—The history of cometary spectroscopy began with the visual examination of the spectrum of Comet 1864 II (Tempel) by G. B. Donati at Florence, Italy, on Aug. 5, 1864. The first slit spectrogram was obtained photographically on June 24, 1881, of Comet 1881 III (Tebbutt) by Henry Draper in New York and by William Huggins in England. Since that time the spectra of about 70 comets have been photographed.

The light from the nucleus and inner coma of a comet is found to consist partly of reflected sunlight and partly of monochromatic emissions characteristic of cometary gases. The composite nature of the light is evident from the spectrograms, which show a continuous spectrum crossed by the familiar Fraunhofer absorption lines (the solar spectrum) upon which emission bands arising from the luminous cometary gases are superposed. In some objects the solar-type spectrum is more intense than the cometary emission bands; in others the reverse is true. Furthermore, for any one comet the intensity of the characteristic emission relative to the solar-type spectrum may vary with changing distance from the sun. At distances from the sun greater than about 3 A.U., normally only the solar-type spectrum is present, unaccompanied by emission features.

The characteristic cometary emissions almost all arise from molecular compounds. The following molecular radicals, nearly all neutral, have been identified in the heads of comets by their radiations:  $C_2$ , CN, CH,  $CH^+$ ,  $C_3$ , NH, OH. The ionized radicals  $CO^+$ ,  $N_2^+$  and  $CO_2^+$  are the principal contributors to the light of the tail. No unambiguous evidence exists for the presence of neutral molecules in comet tails. Other radicals which may be present in comets, but for which evidence was not sufficient in the late 1950s for positive identification, are  $NH_2$ ,  $NH_3$ ,  $OH^+$  and  $CH^+$ . All of these compounds, although not chemically stable in the sense that they would instantly combine with others under terrestrial conditions, are physically stable in a very rarefied gas such as exists even near the nucleus of a comet. The emissions of the head have fairly definite extensions; for example, the CH bands are concentrated toward the nucleus, whereas the CN and  $C_2$  bands extend throughout the whole head. The  $C_2$ , CN and CH molecules were identified in comets many years ago and the  $CO^+$  and  $N_2^+$  bands somewhat later. Identification of all other molecular emissions mentioned was made after 1940, and certainty of the  $C_3$  identification was established only after 1950.

Atomic emission lines occur in the spectra of the heads of comets much less frequently than do molecular emissions, and generally only when the comet approaches the sun to within less than 0.5 A.U. The elements identified in atomic form by their spectral lines are sodium, iron, oxygen and probably nickel.

The mechanism by which the gaseous molecules in the comet produce the characteristic emission bands is a very interesting one. As early as 1911 K. Schwarzschild and E. Kron suggested that the bands were produced by resonance or fluorescence, the exciting radiation being sunlight. In the resonance mechanism, molecules in the comet absorb solar radiation and re-emit light of almost exactly the same wave length. In fluorescence the molecules absorb light and re-emit at longer wave lengths (e.g., absorb ultraviolet light and re-emit in the visible region). Rather definite proof that the mechanism of emission is resonance rather than fluorescence came from two independent lines of evidence. Most of the emission bands observed in comets show intensity distribu-

tions of the lines of the rotational fine structure that are markedly different from those found in the laboratory. The stronger bands, most particularly the violet CN bands, have been studied in considerable detail. In 1941 P. Swings, supposing the bands arose by pure resonance, showed that the uneven intensity contour of the exciting solar radiation, caused by the presence of strong Fraunhofer absorption lines, offered an explanation of the observed effects. Densities of material both in the coma and in the tail are exceedingly low, never more than  $10^6$  molecules per cubic centimetre, usually very much less, and collisions are completely negligible. No redistribution of energy can occur, therefore, and the population of the various rotational levels is determined entirely by the profile of the solar spectrum, displaced as a result of the radial velocity of the comet relative to the sun. The correctness of this picture was strongly supported by quantitative intensity measurements on the CN bands of comets 1939 III and 1941 I by A. McKellar in 1942. Additional evidence obtained from high-dispersion spectra procured later supports the earlier conclusions in detail. The second line of evidence came from an almost concurrent investigation by Y. Öhman of the polarization of light in the stronger emission bands in the spectra of comets 1941 I and 1941 IV. He found that the amount of polarization observed was that to be expected if the bands were produced by resonance. This conclusion was fully confirmed by later results. No mode of excitation other than resonance has been demonstrated observationally to take place. If solar corpuscular streams are of importance in the formation of certain types of tails, some molecules may be excited to radiate by collisions. Evidence for collisional excitation may be found when some of the weaker bands can be photographed with sufficient resolution to permit study of the relative intensities of the rotational lines.

**5. Comet Models.**—After 1950 a fairly consistent picture of the structure of comets developed around the "icy conglomerate" model proposed by Whipple. His model was an extension of suggestions made by earlier investigators combined with some very original ideas. The nucleus is thought to consist of a conglomerate of various ices, hydrates and radicals of the lighter elements, primarily hydrogen, carbon, nitrogen and oxygen, combined with a background matrix of heavier meteoric elements. The nuclei of different comets are thought to range in diameter from several kilometres to negligibly small. Eventually the nuclei undergo complete dissolution through the continuing loss of material as a result of solar radiation. Material near the centres of large nuclei is likely to be relatively more compacted by pressure than is material near the surface or in smaller nuclei, but it is all very fragile. There are differences in composition and density from comet to comet. As the more volatile materials are lost by sublimation, desorption or sputtering caused by electromagnetic or corpuscular radiation from the sun, the meteoric material forms a protective crust that insulates the substance below from further rapid attack. Uneven loss of material and the formation of jets can be explained by local breakdown of the crust in weak spots. Eventually the remains of the nucleus are pictured as a meteor swarm composed primarily of the heavier meteoric elements of the original mass. To permit the accumulation of free radicals, cometary nuclei would have to be formed at places where the density was extremely high compared with the densities of interstellar material, and probably in places where the temperature was less than  $30^\circ\text{K}$ .

The coma would be formed by escape of volatile materials from the mass under the influence of solar radiation as the comet approached the sun. Fragments of solid particles presumably would be carried along with the gases and be the source of the solar-type spectrum of the inner coma and occasionally of the outer coma and tail. The icy conglomerate model has presented some difficulties arising from the fact that the vapour pressures of solid  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{CH}_4$ ,  $\text{C}_2\text{H}_2$ , etc., differ by large factors and the model cannot explain the order of appearance with decreasing heliocentric distance of radicals observed spectroscopically. The trouble can be overcome by assuming the presence of solid hydrates, since these have rates of sublimation of the same order of magnitude. In all cases more complicated "parent" molecules are photodissociated to produce the observed radicals.

A somewhat different model of a comet has been proposed by R. A. Lyttleton and others. In their view a comet is composed entirely of small particles, the impression of a nuclear condensation being caused only by the increasing density of particles toward the centre of the swarm. Production of the coma and tail is thought to be caused by collisions between particles of the swarm, the frequency of collisions increasing, for dynamical reasons, in the vicinity of perihelion. Collisions would cause fragmentation of some of the particles, leading to more rapid liberation of gases as well as to an increase in the number of particles small enough to be dominated by solar radiation pressure. The chemical composition of the particles is essentially that of the interstellar medium, from which Lyttleton suggested the comets were formed. Compounds of hydrogen, carbon, nitrogen and oxygen, plus an admixture of metallic constituents, principally iron, make up the bulk of the material. The composition thus resembles closely that of the icy conglomerate model.

Though the appearance of some comets is quite consistent with the particle-swarm picture, other comets present strong evidence for the presence of a rather substantial nuclear body, as was mentioned above.

### III. ORIGIN AND EVOLUTION

**1. Origin of Comets.**—Ideas of the mode of origin of comets fall into three groups: (1) eruptions from the major planets or from their larger satellites (proposed first by J. L. Lagrange in 1814, modified by others and revived by S. K. Vessviatsky in 1931 and 1952); (2) capture from interstellar space (suggested first by P. S. Laplace in 1813, presented by others in modified forms and revived in an entirely new fashion by Lyttleton in 1948); (3) formation at the time of origin of the solar system in the same general region where the planets were formed (J. H. Oort, G. P. Kuiper and others). Despite the fact that substantial progress has been made on the problem of the origin of comets, definite answers are not available, and previously generally accepted notions have had to be revised continually in the light of new ideas.

The existence of many short-period comets having aphelia (outermost points) near the orbit of Jupiter long ago led to the suggestion that comets might be formed by ejection of material from that planet. Modern knowledge of the constitution and physical characteristics of the major planets and of their satellites casts doubt on the possibility of such violent eruptions as would lead to the escape of material from these very massive planets. The history of the orbits of the known comets that have experienced very close approaches to Jupiter is not consistent with an eruptive origin, nor can the existence of great numbers of parabolic comets be satisfactorily explained in such a way.

Though very convincing arguments in the past have led to the rather generally held conclusion that comets have always been members of the solar system, suggestions made by Lyttleton regarding capture from interstellar dust clouds have made it difficult to reject the possibility of interstellar origin. Lyttleton suggested that as the sun passed through a dust cloud, a large increase in the space density of particles would occur along the accretion axis (i.e., along the velocity vector of the sun relative to the cloud) following the sun. Collisions between particles would lead to disruption and melting of some of them and to dissipation of energy. Elliptic orbits could arise for some particles from head-on inelastic collisions involving destruction of the transverse component of velocity. The probability of collisions would increase in time with accumulation of material along the accretion axis. Particles close to the sun would be captured while particles at large distances would escape, the "capture radius" depending largely on the velocity of the sun relative to the cloud. Lyttleton calculated that tens of thousands of cometlike swarms of particles could be captured during passage of the sun through a single cloud. Initial orbits of nearly all the new comets would be very elongated ellipses, the comet passing at first very close to the surface of the sun and receding to distances of several hundred A.U. The largest comets would be formed at distances near the capture radius and would, on the average, recede to

greater distances at aphelion than would smaller objects. The effect of perturbations, both stellar and planetary, would modify the original orbits considerably in the course of time. According to Lyttleton, comets are composed entirely of small particles, and the newly formed objects would be completely vaporized at the first perihelion passage except in most unusual cases. As the comet receded from the sun it would recondense into a swarm of small particles. Capture of comets from interstellar clouds would provide a means of occasional replenishment of the solar system supply of these objects. Sufficiently detailed analysis has not been made of the mechanics of the capture process to determine whether cometlike objects could be formed in the manner suggested, or whether known characteristics of cometary orbits could be satisfactorily explained by it.

Another suggestion regarding the origin of comets is that they, as well as the minor planets, are remnants of a planet spoiled in the making or somehow destroyed subsequently in the region between the orbits of Mars and Jupiter. An alternative possibility is that comets were formed during contraction of the solar nebula in the region outside the orbit of Neptune, where, it has been suggested, the density of material was too low for the formation of a large body.

Interesting evidence derived from analysis of the present nature of comets and of their orbits, and bearing ultimately on cometary origins, was presented by A. J. J. van Woerkom, Oort and M. Schmidt in a series of papers that appeared between 1948 and 1951, extending the work of earlier investigators. The main part of their investigation was based on a study of certain characteristics of the orbits of all nearly parabolic comets that were sufficiently well observed between 1850 and 1936. The statistical distribution of the values of the original  $1/a$  ( $a$  = semimajor axis of the orbit), freed from the influence of perturbations in the region of the planets, was examined. It was found that comets are now coming into the vicinity of the sun from distances of 40,000 to 150,000 A.U. The effect of planetary perturbations during even a single previous close approach to the sun would produce a much broader peak in the distribution than was found, and it was deduced, therefore, that these comets were coming near the sun for the first time. Oort concluded that there is a vast reservoir of comets trapped in a sort of deep-freeze storage at the fringes of the solar system. The action of stellar perturbations (the nearest star is at a distance of about 300,000 A.U. from the sun) occasionally sends one of perhaps  $10^{11}$  comets from storage into the region of observability near the sun. Oort and Schmidt called attention to various physical differences between the new comets and old ones that had been close to the sun before. These include differences in rate of disruption, in rapidity of brightening on approach to the sun and in relative strengths of the solar-type and characteristic emission spectra, especially at distances from the sun greater than one A.U. There also may be a greater tendency for new comets to display double or multiple tails. The comets in storage, whatever their origin, share the sun's motion very exactly and definitely are members of the solar system though they are perturbed by the nearby stars. They have been in storage long enough for stellar perturbations to have stirred their orbits thoroughly, and the orbits give no indication of a residual preferential orientation of their lines of apsides.

In regard to the mode of formation of the comets, Oort theorized that they, the major planets and the asteroids might have originated together in the inner regions of the solar system, while Kuiper conjectured that comets condensed from the solar nebula just outside the region of formation of the major planets. Lyttleton's theory of capture from interstellar clouds implies that comets may be formed at distances from the sun of up to 1,000 A.U. Oort demonstrated that whatever their origin, bodies moving in very eccentric or highly inclined orbits in the inner regions of the solar system will gradually be diffused outward by the effect of planetary perturbations, just as comets now on the outer fringes of the solar system are diffused inward by stellar perturbations. In the outward diffusion a large fraction of the original bodies (nearly 90% according to Oort) were lost to the solar system and became interstellar wanderers, but the remainder were caught in

the reservoir. Objections to this picture have been raised on the grounds that a very large population of interstellar comets would be produced, considering the contributions of other solar systems, and comets with strongly hyperbolic orbits should be observed occasionally. No such comet had been observed by the late 1950s.

The several dozen known comets of short period all pass at some time close to the orbit of Jupiter and undoubtedly were captured by that massive planet from orbits that probably closely resembled those of comets that now travel from the fringes of the solar system. Details of capture depend strongly on particular circumstances, and the large changes cannot be discussed in a statistical way. It has been stated that the number of close approaches to Jupiter of comets moving in orbits of long period is insufficient to account for the present number of short-period comets. Average lifetimes often adopted for these comets have been much too brief, however, and evidence is accumulating that at least some comets survive thousands of years of repeated perihelion passages and close approaches to massive planets.

**2. Gradual Diffusion of Cometary Matter.**—Cometary material is gradually scattered by at least two processes. Finely divided matter in the coma and tail is dissipated by nongravitational forces that cause a small continuous loss of mass. Accretion near aphelion cannot make up the loss for observed comets even in the most favourable circumstances. Dispersion of meteoroids away from the nucleus is caused by differing gravitational attractions of perturbing planets on individual meteoroids. The process accelerates as the separations increase but, even so, the large dispersion of some meteor swarms away from the parent body must have taken a very long time. The long time scale of the gravitational disruption is in itself an argument for much longer lifetimes of comets than have sometimes been suggested. The role of internal forces should not be neglected as an initial step in the process of dissolution. Comets may cease to exist as such when all volatile materials have been lost and they no longer are able to produce a coma, or when the nucleus has been reduced to such a scattered swarm of meteoroids that all semblance of unity and coherence has been lost.

#### IV. ORBITS OF COMETS

**1. Law of Gravitation Applied to Comets.**—It was impossible to ascertain the true nature of the orbits of comets until the law of gravitation had been established. Isaac Newton proved that, under a force that varied in proportion to the inverse square of the distance, a body would move in one of the family of curves known as conic sections; that is, the circle, ellipse, parabola or hyperbola. It was soon recognized that the observed movements of comets could be explained on the hypothesis that they were traveling around the sun in elongated ellipses or parabolas, being visible only when they described the small portion of their orbits in the neighbourhood of the sun. Newton himself applied the new principle to the brilliant comet of 1680; subsequently he obtained the assistance of Edmund Halley, who in 1704 collected the observations of 24 comets, commencing with that of the year 1337, and calculated their orbits. On studying the orbits, Halley noticed that three, those of the comets of 1531, 1607 and 1682, were practically identical. The interval between appearances of the comets were not the same, the first being longer by 15 months, but Halley saw that the differences could be readily explained by the disturbing action of the large planets Jupiter and Saturn. Examination of the records then revealed another appearance of the same comet in 1456. It was confidently assumed that all four apparitions belonged to a single object, whose return might be expected about 1758. The comet did in fact return in 1759, and again in 1835 and 1910, establishing for the first time the fact of a comet's return. This comet is now known as Halley's comet; the next apparition is expected in 1986.

**2. Comets of Short Period.**—Halley called his comet a "Mercury among comets," supposing that it had the shortest period of any; this has been known to be incorrect since the discovery of Encke's comet early in the 19th century. By the early 1960s there were over 80 known comets with periods of less than 100 years.

Of these over 60 had periods of between three and nine years. The short-period comets form a very homogeneous group of objects, all revolving around the sun in the same direction as do the major planets, in orbits of low inclination to the plane of the earth's orbit. The aphelia of their orbits all lie close to the orbit of Jupiter. The evidence that these comets were captured by Jupiter from more elongated orbits is overwhelming, and they are considered to be part of "Jupiter's family" of comets.

Efforts have been made by some investigators to establish subdivisions among the somewhat smaller number of comets having periods ranging from 10 to about 150 years and assign them to other major planets as "families." H. N. Russell showed in 1920 that the evidence for the reality of families of comets belonging to Saturn, Uranus, Neptune or more distant planets was very weak. Most comets assigned to the outer planets almost surely were captured from very elongated orbits by Jupiter.

Though a few instances were known prior to 1819 in which a parabolic orbit failed to satisfy the observations of a comet and an elliptical one was deduced, inaccurate observations usually led to a weak determination of the period that failed to be verified by observation of the comet at the next return. On Nov. 26, 1818, Jean Louis Pons, an assiduous comet hunter at Marseilles, France, found a telescopic comet that was observed for 40 days; J. F. Encke, a celebrated German astronomer, undertook the study of its orbit and found that it was an ellipse with a period of 3.3 years. This is still the shortest confirmed cometary period, though an estimated period of 2.3 years was found for Comet Wilson-Harrington (1949 III), which was observed for only six days in Nov. 1949. Encke was able to prove, by laborious calculation of the disturbances caused by Jupiter, that the comets seen in 1786, 1795 and 1805 were identical with the one of 1818; he predicted the circumstances of its return in 1822, and these were exactly verified. From that day to the present time the comet (which bears Encke's name because of the enormous amount of work he performed on it) has been observed at every return except that of 1944. There are two reasons for the nearly unbroken record of observations of Encke's comet. One is that it passes within 0.34 A.U. of the sun, much closer than do any of the other short-period comets, and hence is moderately bright and easy to observe. The other is that a succession of able mathematicians—Encke, F. E. von Asten, Oskar Backlund, S. G. Makower—have calculated the disturbances of its orbit. A peculiarity noticed by Encke was that, after allowances for planetary perturbations had been made, the period was shortening by about  $2\frac{1}{2}$  hours each revolution. It was suggested that such an effect might be produced by a resisting medium that would cause the comet to lose energy and travel in a smaller orbit. The effect has decreased progressively and very markedly, however, and was extremely small in the mid-20th century. The acceleration may possibly be explainable by observational effects combined with modifications of planetary perturbations introduced by slightly different starting orbits, values of the masses of the planets or planetary co-ordinates. A few other short-period comets have been suspected of showing slight accelerations or retardations, though no case is beyond doubt. It has been pointed out that small effects could be produced by non-uniform ejection of material from cometary nuclei, and that if the nucleus was rotating, a secular acceleration or retardation would depend on the sense of the rotation.

**3. Comets of Long Period.**—Unless a newly discovered comet is of the short-period type, observations are generally satisfied for a considerable time by an orbit that is assumed to be exactly a parabola. Such comets are sometimes spoken of as parabolic comets. However, like the circle, a parabola is a very special curve, and even if a comet followed one exactly for an instant, it would not continue to do so because of the disturbing effects of planetary perturbations. In practice, moreover, over the small part of the whole orbit in which the comet can be observed, the difference between a very elongated elliptic or slightly hyperbolic orbit and an exactly parabolic orbit is hardly distinguishable. Determination of the other elements of the orbit often is strengthened by assuming exactly parabolic motion, because one fewer unknown is then to be determined from the observed quantities.

Normally this assumption is very sound. Eventually, when all observations have been made and the comet has disappeared from view, a definitive orbit is calculated, including a determination of the eccentricity of the orbit. Not infrequently the uncertainty of the determination of the eccentricity is more than the difference between the value of the eccentricity found and a value of exactly one, which corresponds to a parabola. Planetary perturbations may also cause a comet to have a hyperbolic velocity while it is close to the sun, whereas it may have approached the region of the planets in an elliptic orbit. Original orbits of a number of "hyperbolic" comets have been investigated, principally by E. Strömberg, and in every case the original orbit of approach to the sun was found to be an ellipse when the effect of the planetary perturbations was removed, within the uncertainty of the determination. A certain percentage of comets approaching the sun along elliptic orbits are in fact forced into hyperbolic orbits by planetary perturbations, however, and these comets leave the solar system forever. One must conclude that all comets yet observed, whatever their origin, have been members of the solar system for an appreciable time.

**4. Discovery and Observation of Comets.**—Most new comets are discovered by professional astronomers on photographs taken with wide-field telescopes for programs not connected with cometary research. Some comets are found as the result of systematic searches by amateur and professional astronomers, but many hours of searching are usually required for one comet discovery. Returns of periodic comets can be predicted, however, and generally only a very limited area in the sky need be examined to ensure recovery of the comet when it becomes sufficiently bright. Such comets are normally recovered when they are still very faint and at large distances from the sun. The brightest of new comets often are first seen very close to the sun in the sky, a region neglected by professional astronomers. Hence they are often found by a casual observer as he looks at the sky at sunset or sunrise. Suspected comet discoveries should always be reported promptly to the nearest astronomical observatory for confirmation and communication of the time of observation, position, rate and direction of motion, brightness and a description of the appearance of the object to astronomers throughout the world.

See also ASTEROIDS; METEOR; PLANETS.

**BIBLIOGRAPHY.**—Nearly all textbooks on astronomy contain chapters on comets. The references given below are only to books dealing specially with them. Of popular character are: George F. Chambers, *The Story of Comets* (1909); Mary Proctor and A. C. D. Crommelin, *Comets* (1937); Fletcher G. Watson, *Between the Planets* (1936). Books of somewhat more technical character are: J. G. Porter, *Comets and Meteor Streams* (1952); R. A. Lyttleton, *The Comets, and Their Origin* (1953); Nikolaus B. Richter, *Statistik und Physik der Kometen* (1954). Each of these books contains an extensive bibliography. An excellent chapter on comets by N. T. Bobrovnikoff appears in J. A. Hynek (ed.), *Astrophysics* (1951). Many references are given. Cometary spectra are discussed by P. Swings in A. Beer (ed.), *Vistas in Astronomy*, vol. 2 (1956), and P. Swings and L. Hasegawa in *Atlas of Representative Cometary Spectra* (1956). Extensive bibliographies are given in both of these works. Orbit computation is discussed in: R. T. Crawford, *Determination of Orbits of Comets and Asteroids* (1930); P. Herget, *The Computation of Orbits* (1948). Both of these books contain references in the text to technical papers on various aspects of orbit computation. F. Baldet and G. de Obaldia, *Catalogue général des orbites de comètes de l'an —466 à 1952* (1952) lists elements of orbits of comets and gives references to earlier orbit catalogues. (E.H.R.)

**COMET SEEKER**, a small telescope specially designed for use in searching for comets. As comets are usually diffuse bodies with low surface brightness, the essential feature of a comet seeker is a large ratio between the diameter of the lens and its focal length. In ordinary refracting telescopes this ratio is usually about 1:18, while in the comet seeker it is often 1:10 or greater. The focal length of a comet seeker is usually small, for ease of operation, and seldom exceeds five feet. The diameter of the lens is then six inches. The field of view should be at least one degree in diameter.

The comet seeker is supplied with an equatorial mounting and roughly graduated circles. The usual method is to sweep the sky from horizon to horizon in circles of declination, each sweeping overlapping somewhat the preceding one. Coming across a diffuse object the observer compares the field with an appropriate map

of the sky to see that it is not a recorded nebula. A comet betrays its nature by motion in reference to the background stars.

(N. T. B.)

**COMIC STRIP**, a series of drawings published or done for publication and presenting a narrative, which may or may not be humorous. The progenitors of comic strips are to be found in such works as William Hogarth's *A Harlot's Progress* (1731) and *A Rake's Progress* (1735), or Wilhelm Busch's *Max und Moritz* (1858). The modern comic strip rose in New York and Chicago newspapers between 1894–96 and 1907 from contributions of its diverse characteristics by R. F. Outcault, James Swinnerton, Rudolf Dirks and Clare Briggs. See **CARICATURE AND CARTOON: Comic Strips**.

**COMILLA**, a town and headquarters of Comilla district in the Chittagong division, East Pakistan, is situated on the Gumti river 53 mi. E.S.E. of Dacca, on the main road and railway from Dacca to Chittagong. Pop. (1961) 54,504. It is protected from inundation by an embankment along the bank of the Gumti. The town is on low land and drainage presents great difficulties, the streets being below the level of the river when it is in flood. There are about 400 tanks in the town and its environs, some of which are reserved for drinking water. The splendid Dharmasagar tank, a mile in circumference, was constructed by a raja of Tippera in the 15th century. Comilla is a collecting centre for hides and skins. It has a small match factory and a thermal power station. Cane and bamboo basketry is the main cottage industry. Though poor in appearance, the bazaar is well laid out with wide streets. There is an old public library established in 1885. Victoria college is affiliated with Dacca university and is the seat of the East Pakistan academy for village development.

Comilla district has an area of 2,594 sq.mi., and a population (1961) of 4,388,906.

(K. S. Ad.)

**COMINES, PHILIPPE DE**: see **COMMUNES, PHILIPPE DE**.  
**COMINFORM**, a name given in the west to the information office of the Communist parties (*q.v.*). This was an agency of international revolutionary Communism from 1947 to 1956. It was formed in Sept. 1947 at Wilcza Gora, Pol., by representatives of the Communist parties of the U.S.S.R., eastern Europe, France and Italy. On June 28, 1948, the Yugoslavs were expelled from the organization. On April 17, 1956, the Cominform was dissolved, probably to help to improve relations between the U.S.S.R. and Yugoslavia.

See **INTERNATIONAL, THE; COMMUNISM**.

**COMINTERN**, the Communist or Third International, established in March 1919 in Moscow to foster the spread of world Communism. It was officially dissolved on May 22, 1943. See **INTERNATIONAL, THE**.

**COMITIA**, the term applied in ancient Rome to formal elective and legislative assemblies of the Roman people, is the plural of *comitium*, the early "meeting place," and is distinct from *concilium* and *contio*. *Comitia* were organized in regular groups, *curiae*, *centuriae* ("centuries") or *tribus* ("tribes"), and had to be held on a proper calendar day (*comitialis*), after the taking of auspices and on an inaugurated site (see **AUGUR**). A *concilium* was a meeting of only a part of the people, such as the plebeians, and a *contio* was a public meeting open to all the people for announcements or discussion. But *comitia* came to mean "elections" and was sometimes used of the *concilium* of the plebeians. *Comitia* were summoned only to secure a binding vote on business presented by a presiding magistrate who had the right to act with the people. They could not discuss or amend it. In spite of differences in composition according to the groups in which the people had been organized, and the fact that the patricians were not members of the *concilium plebis*, all the assemblies became valid organs of the expression of the will of the people. They were theoretically sovereign but in fact were limited by the reservation of initiative to the magistrate, the veto of his colleagues and the actual authority of the senate. The early requirement that all acts be formally ratified by the patricians in the senate (*patrum auctoritas*) was reduced to a matter of form in the 4th century B.C. when it had to be given before a law was put to the vote. The major assemblies were the following:

**Comitia Curiata**.—This was the ancient assembly of 30 *curiae* dating from the period of the kings (see **CURIA**). It met in the *comitium*. In the republic it was politically unimportant, yet formally necessary for the passage of the law which formally granted *imperium* to magistrates (*lex curiata de imperio*). It also met in the Curia Calabra under the *pontifex maximus* to ratify wills and adoptions, to hear religious announcements and to witness the installation of priests. In historical times the 30 *curiae* were represented by 30 lictors (see **LICTORS**).

**Comitia Centuriata**.—The *comitia centuriata* according to Roman tradition was instituted by Servius Tullius, the penultimate king of Rome, though some date it as late as 450 B.C., as a reform for military purposes. (The *centuria* was the smallest unit of the Roman legion.) All Roman citizens were registered in regional tribes and a census was made of their property. They were then assigned to classes and centuries according to their wealth and the equipment they could provide for military service. From the 5th to the 3rd century B.C. the *comitia centuriata* with its timocratic organization was the major political assembly, presided over only by magistrates with *imperium* and summoned as an army by the military trumpet to meet in the Campus Martius outside the *pomerium* (the boundary within which Roman gods only could be worshipped and civil magistrates rule).

It consisted of 193 centuries, 18 of *equites* (*q.v.*) and 80 in the first and wealthiest class (40 *juniores*, men aged between 17 and 45 years, and 40 *seniores*, between 46 and 60 years). The result was that in the voting, which was by centuries, these two classes had a majority (98) over the combined vote of the other four classes and the supernumeraries (95 in all). About 241 the scheme was adapted to the number of the 35 tribes by assigning a century each of *seniores* and of *juniores* in the first class to each tribe, thereby reducing the number of votes to 70, and a complex recombining of tribes in the centuries of the other classes is revealed by the provisions of the *Tabula Hebana*, an inscription partly recording a *rogatio* in honour of the dead Germanicus (d. A.D. 19). In this rearrangement, in spite of the loss of an absolute majority, the wealthiest classes retained a great advantage, and the assembly remained an aristocratic and conservative body even after the extension of Roman citizenship to Italy, for those who could come to exercise the franchise in Rome belonged mostly to the first class.

The *comitia centuriata* elected consuls, praetors and censors, functioned on appeal as a criminal court in capital cases, and alone had power to declare war. In elections the first century, called the *praerogativa*, at first one of the *equites* but after the reform chosen by lot from all but two of the urban tribes in the first class, had a great influence on the outcome. This assembly was infrequently used for legislation after the rise of the two tribal assemblies with their less cumbersome procedure, and was only briefly restored to primacy in legislation by L. Cornelius Sulla. It continued to elect magistrates under the emperor Augustus, but imperial commendation of candidates and the institution of a preliminary choice (*destinatio*) by senators and *equites* grouped in special centuries made this a formality. It continued to be summoned for the announcement of elections and still met with the old ceremonies in the 3rd century A.D.

**Concilium Plebis**.—This assembly, which was organized and voted by tribes, consisted only of plebeians and could be summoned and presided over only by the plebeian magistrates, the tribunes. It usually met in the forum or on the capitol. If the Roman tradition is correct (that the election of plebeian magistrates was transferred to it in 471) it existed from or before that date. It grew in importance with the rise of the plebeians, though how far its resolutions (*plebiscita*) were binding on all Roman citizens remains uncertain. This principle was finally established by the *Lex Hortensia* of 287. Simpler procedure and the availability of tribunes to introduce measures made the *concilium plebis* the chief legislative body of the middle and later republic. It became also a ready instrument for the demagogic tribunes of the period from the Gracchi onward. It could validate treaties of peace, and interdict a citizen from fire and water, but its judicial functions were regularly limited to fines for noncapital offenses.

**Comitia Tributa.**—In contrast with the *concilium plebis*, the *comitia tributa* was an assembly of the whole people, patricians and plebeians. The date of institution is uncertain, but it elected curule aediles (see *AEDILE*) and legislation is attributed to it in 357. Consuls, praetors and, for purposes of jurisdiction, curule aediles could preside. It met in the forum, on the capitol, and in the late republic also in the Campus Martius. Besides curule aediles, it elected quaestors, *tribuni militum a populo* (see *TRIBUNE*) and other minor magistrates, and became a regular organ for legislation by all the people. Its jurisdiction was limited to offenses involving fines. Both the tribal assemblies were increasingly influenced by demagogic leaders and by bribery as members of the rustic tribes swelled the urban population.

**Other.**—Apart from those listed above, special *comitia* of 17 tribes (one less than a majority) met, with the most recent *pontifex* presiding, to elect the *pontifex maximus*, and after 104 B.C., except from Sulla's dictatorship (82 B.C.) until 63, to elect members of the other priestly colleges, the pontiffs, the augurs and the *quindecimviri sacris faciundis* (see *PONTIFEX*).

The extension of Roman territory and of Roman citizenship too widely for any but a few to attend the *comitia* from distant regions of Italy or the provinces were also factors in the decline of all the *comitia* in spite of the emperor Augustus' provision for local councilors to vote in their towns for Roman *comitia*. The various elective, legislative and judicial functions gradually lapsed under the principate. The last piece of recorded legislation by the *comitia* is an agrarian law carried by the emperor Nerva in A.D. 98.

There were also *comitia* in *municipia* and *coloniae* for the election of magistrates and the passage of local legislation, but authority came to be vested in the councils. These *comitia* also decayed under the empire.

(T. R. S. B.)

**COMITY**, courteous practices between nations, specifically the courteous recognition in one country of the laws and customs of another. Comity (Latin *comis*, "courteous") does not have the force of law, but it may be the source of precedents that develop eventually into law. See *INTERNATIONAL LAW, PUBLIC*.

**COMMAGENE**, in ancient geography, a district in northern Syria whose boundaries were defined by the Euphrates river on the east, Cilicia on the west and Cappadocia on the north. Formerly part of the Seleucid kingdom, it became independent about 162 B.C. when its governor revolted and established a dynasty. Its king Antiochus I submitted to the Roman general Lucullus in 69. In 64 he at first opposed Pompey during the Mithradatic war, but quickly changed sides. After supporting Pompey in the civil war of 49, he joined forces with the Parthians in 38. This king sought to perpetuate his memory by erecting, c. 30, an imposing mausoleum on the peak of Nimrud Dag (Turkey); extensive remains have been discovered. The general state of the country at that time was probably similar to that of Cappadocia; that is to say, feudal, with city life little developed and Greek culture and language making only slow progress beyond the court. Indicative of the mixture of cultures is the fact that the kings traced their descent from both the Seleucids and the Persian Achaemenids. In A.D. 17 the kingdom was annexed to Rome. Under the emperor Caligula (Gaius Caesar) the kingdom was restored (38), but in 72 was again annexed, and incorporated in the Roman province of Syria.

See D. Magie, *Roman Rule in Asia Minor* (1950). (R. H. St.)

**COMMAND**, a word coined from Latin but borrowed into English from the Old French about 1300, still carries something of its early connotation "to place in hand" (*com* + *manus* + *dare*). Both as a verb and noun it lends itself to many uses. Thus one

may command a view, a guided missile (by radio) or a person; or one may exercise command, utter a command, receive a command or be in a chain of command. In one sense, command is the prerogative of a person in authority by virtue of office or of personal prowess. In another, it is equivalent to control or power, as in "he had such command of words as to persuade his enemies." In the military any unit is, from one standpoint, a command; but some units, normally large establishments, are officially called commands, illustrated by the R.A.F. bomber command or the southeast Asia command of World War II or by the continental air defense command, organized in the U.S. in 1954. (Wb. A. H.)

**COMMANDANT**, the commander of a single place or body of men, such as a military school or training unit, or of a larger organization such as a naval district in the United States. In the British army the term colonel commandant refers to the senior officer of a regiment. In the French army a commandant is the commanding officer of a battalion, a rank equivalent to major. Headquarters commandant is a special use of the word to denote a staff officer in charge of the internal administration of a military headquarters, often with emphasis on maintenance and security of buildings and grounds.

The rank of a commandant depends upon the size and importance of his command. The commandant of the U.S. marine corps, for example, is a four-star general and the commandant of the U.S. coast guard is a vice-admiral. (H. C. T.)

**COMMANDMENTS, TEN:** see *DECALOGUE*.

**COMMANDO**, a Portuguese word meaning "command," adopted by the Boers in South Africa for military and semimilitary expeditions against the natives. More particularly a commando was the administrative and tactical unit of the forces of the former Boer republics, "commandeered" under the law of the constitutions, which made military service obligatory on all males between the ages of 16 and 60. Each commando was formed from the burghers of military age of an electoral district. These citizen units fought effectively in the South African War of 1899-1902.

In World War II the name was applied by the British to "specially-trained troops of the hunter class," formed in the first instance for raids against enemy-occupied coasts. Their counterparts in the U.S. forces were known as rangers or marine raiders. The first such troops in the British services were organized in June 1940, largely on the initiative of Winston Churchill; the name commando and plans of organization were suggested by Lieut. Col. Dudley Clarke. The distinctive commando symbol later came to be the green beret.

Popular usage to the contrary, a commando was not an individual, but a unit roughly equivalent to an infantry battalion. In the beginning commandos were formed of volunteers from army units; from 1942 onward they were also formed from the Royal Marines. Commandos served with notable distinction in various raids, including that on Dieppe, Aug. 19, 1942, and in the campaigns in the Mediterranean and northwest Europe. After World War II the commando role was reserved exclusively for the Royal Marines, and one Royal Marine commando fought in the Korean campaign. See *INFANTRY: World War II: Special Types of Infantry*.

**COMMEDIA DELL'ARTE**, an improvised theatrical production that originated in Italy in the 16th century, flourished until the early 18th century and influenced modern theatre in several important ways.

**Early Development.**—Semipermanent troupes of traveling actors first brought the *commedia dell'arte* to the place of performance (theatre, public square, banquet hall); their repertory of plays, generally comic, was derived principally from classical or neoclassical literary drama. Each member of the troupe played a particular masked stock character; the performance was more or less improvised on a skeleton plot (scenario) in the presence of the spectators. The genre name, loosely translated as "comedy of the professionals," distinguishes the production from the largely amateur, academic, literary drama of the period.

The origin of the form is obscure; attempts to trace it from

prehistoric mime and farce through the dark ages to the Italian Renaissance have failed. Certain social and cultural conditions, however, generally have led professional entertainers in all ages to create a similar form by adding stock characters and situations to their acrobatic displays.

The earliest date associated with an Italian *commedia* troupe is 1545. The Gelosi, headed by Francesco Andreini and his wife Isabella, is the most famous of the early companies, but there were many others during the next century and a half, and both scenarios and stock characters were handed down from their 16th century creators to their 17th century successors. The fame of the companies brought them invitations to perform throughout western Europe. Shakespeare and Ben Jonson in England and Molière in France were the principal non-Italian authors who came under the influence of *commedia dell'arte*, while the Italians Carlo Goldoni and Carlo Gozzi created a literary drama out of its 18th-century remains.

The typical *commedia* company had a stock of scenarios, some commonplace books containing soliloquies and witty exchanges appropriate to various situations and appropriated from various authors, and about a dozen actors, each with his own "mask" or stereotype character.

**The Masks.**—While each company may have had its special name for the stock types, in general the cast of a play would require the services of: (1) Pantalone (Pantaloön), a lecherous, miserly Venetian magnifico, the parent or guardian to be outwitted by the young lovers, wearing a half mask with a long, sharp, hooked nose, a flat cap and the trousers to which he has given his name. Shakespeare, in *As You Like It*, describes the next to last of the ages of man as "the lean and slipper'd pantaloön." (2) Dr. Graziano, a second parent-character, gullible and amorous, given to malapropism and generally burlesquing some profession, such as the law or medicine. (3) Capitano, the braggart warrior and arrant coward, with the bristling mustaches associated with Spain and dramatic stories of his impossible military feats. A later manifestation of this character is called Scaramouch; he is not necessarily of the military profession but is a boaster whose weakness is exposed by the low comedians. (4) The *sanni*, servants or men of the lower classes, shrewd, impudent and witty, responsible for much of the broad comic action with their jokes and often irrelevant but amusing tricks (*lazzi*). Among the *sanni* were Arlecchino (Harlequin), Mezzetino, Brighella and Pulcinella (Punch). (5) The lovers, unmasked, the colourless necessary cogs in the dramatic machine. Of these only Colombina (Columbine) has remained alive in theatrical tradition.

By the early 18th century the *commedia* had lost its vitality in Italy, but certain elements of the genre found a new life in other countries. In England, John Rich created from it a new form, which he called Pantomime (*q.v.*), that involved the magical exploits of Harlequin, who was transformed from a vulgar serving-man into a mute dancing creature in eternal pursuit of his sweetheart, Columbine. In the 19th century, largely because of the great clown Grimaldi, English pantomime became a kind of musical comedy with topical satire, spectacular transformations and a fairy-tale plot; it is still the traditional Christmas holiday entertainment in the British theatre. A company of acrobats carried Rich's Harlequin pantomime to Copenhagen in 1801 where they developed a repertory of mute comedies in which Harlequin and Columbine were joined with folk stereotypes drawn from the comedies of Ludvig Holberg. Many of these pantomimes are still in the repertoire performed every summer by the company of the Peacock theatre in Tivoli. The French romantic theatre of the 19th century adopted, as Pierrot, the old *commedia* clown Pedrolino, with his loose white costume and conical hat, gave him a sad, white face and made him a character of infinite pathos; he plays a leading role in Leoncavallo's modern opera *Pagliacci*. Pulcinella found his way into the violent and often cruel puppet play of Punch and Judy. The brief comic plays about stock characters featured in American vaudeville and burlesque, and the two-reel comedies of the silent films (especially the comedies of Mack Sennet), may be called the latest generation of the *commedia dell'arte*.

(A. S. Dr.)

**COMMENDATION**, approval, a recommendation of one person to the favour of another. *Commendatio animae* is the liturgical term for the office commending the souls of the dying and departed to the mercies of God. In feudal law it was applied to the act by which a freeman placed himself under the protection of a lord.

In ecclesiastical law the commendation or grant *in commendam* of benefices was made temporarily until a vacancy was filled, frequently to persons who, by defect of age or orders, were for the time being debarred from receiving institution. The practice of granting benefices *in commendam* to laymen, or, in the case of monasteries, to secular clerks who enjoyed their revenues and privileges for life, or to bishops to hold with their sees, became very general in the later middle ages.

**COMMENTARIUM**, among the Romans, originally notes to assist the memory, memoranda, in domestic and public business. A household kept a diary and account book; e.g., Trimalchio's daybook mentioned by Petronius Arbiter. Public men had notebooks for speeches, legal cases and items of general business. The official use of *commentarii* developed in the priestly colleges to list the details of ceremony and ritual; e.g., in the *Commentarii Pontificum*. This development was an early one, but not so early that the *Commentarii Regum* (Records of the Kings) can be accepted as authentic. The magistrates, too, had their regular notes, e.g., *commentarii consulares*, *ensorii*, *aedilium*, which enabled them to maintain and pass on the routine of their office. This was important for provincial governors, who also submitted reports to the senate.

Under the empire the *Commentarii Principis* were a register of the administrative acts of the emperor, including constitutions, rescripts, epistles and edicts, all set down with official authority. There were also *commentarii diurni*, a court journal, which later became a system of records known as *ephemerides*. Imperial departments had archives that were under the charge of an official entitled a *commentarius*. The *Commentarii Senatus* mentioned in Tacitus' *Annals* probably represent the *Acta Senatus* (minutes of the senate's meetings).

Memoranda could become memoirs, as public men of noble family drafted personal records of their achievements for the domestic archives. By the 2nd century B.C. such memoirs were written as the raw material of history (see ANNALISTS), and much information, often distorted for the greater glory of the family, is derived from these sources. Sulla and Cicero left memoirs as an aid to the historian, and when Caesar published his *Commentarii* for propagandist purposes, his elegant Latinity transformed them into a literary form in their own right. With Augustus, Tiberius and the younger Agrippina this led to imperial autobiography.

**COMMERCE, DEPARTMENT OF:** see GOVERNMENT DEPARTMENTS: United States.

**COMMERCE, HISTORY OF.** Although the term is often used in a wider and less precise sense, commerce means primarily the exchange of commodities conducted on a wide scale and involving transportation over considerable distances. Commerce and trade are in this sense often used interchangeably, but the former stresses the mercantile or free enterprise aspect of these activities, their profit-seeking and risk-taking character, while the latter points more to the physical character of the services performed. This distinction is clear, on the one hand, in the meaning of the adjective commercial, which stands for most of what is characteristic of business in general, and on the other in the use of the

plural trades to include the different manual skills practised by persons in an employed position. It is the same slight distinction that makes one speak of commerce when considering transactions in a free market and to change to trade when the same activities become subject to governmental control. In conformity with this usage, the spontaneous activities of traders are discussed in this article. (For such topics as international trade policies and statistics, see INTERNATIONAL PAYMENTS; EXPORTS; TRADE, INTERNATIONAL; etc.)

It has been truly said that commerce begins "where civilization begins." Even the first great steps in the growth of civilization were dependent on essential materials such as flint and metals being brought to people, usually over long distances. The early phases of civilization known by such terms as the Bronze Age and the Iron Age were dependent on materials found only at a few localities and regularly carried over wide regions. Archaeological discoveries of hoards of such objects as flint axes and amber trinkets suggest that at an early time a form of dealing in such commodities was carried on by persons specializing in these tasks. Even certain kinds of food that were found only at particular localities, such as salt-water fish, were in prehistoric times regularly transported and presumably exchanged over considerable distances.

In the near east and Europe, at any rate, civilization at an early stage was based on the utilization of the dispersed resources of a whole continent and remained dependent for its preservation on the continuance of this commerce. Many of the major changes in history undoubtedly were the results of the interruption of established trade routes; nothing perhaps illustrates better the extent to which a decline of commerce inevitably brings about a decline of civilization than the fact that the great metal shortage which arose when commerce dwindled with the decline of the Roman empire caused most of the great bronze works of ancient Greek sculpture to be melted down, and thus lost to posterity.

This account of the development of commerce is subdivided as follows:

- I. The Ancient World
  1. Phoenicians and Greeks
  2. Commerce of the Roman Empire
  3. Byzantine Empire
- II. The Middle Ages
  1. Italian Trading Towns
  2. Hanseatic League
  3. Characteristics of Medieval Commerce
- III. The Early Modern Period

  2. Sea Route to India
  3. Rivalry of England and Holland
  4. Mercantile System
  5. Industrial Age
- IV. The 20th Century
  1. Development After 1914
  2. Trends After World War II

### I. THE ANCIENT WORLD

The history of commerce is closely connected with the development of the techniques of transportation and communication. Long-distance trading apparently developed first along desert routes which were advantageous in that comparatively large groups could travel together in caravans and defend themselves against marauders. Oases could be used as ports of call and depots. In this way trade sprang up between two of the oldest civilizations in the river valleys of Mesopotamia and Egypt. A large caravan was required to convey 100 tons and its progress was slow. Therefore, the goods which entered this trade had a high value in proportion to their bulk. They included such things as oriental spices, drugs and dyes as well as fine textile fabrics and a variety of metal ornaments; necessities played a subordinate role. Caravan trade retained its essential characteristics for centuries. In the course of time, however, it became subordinate to commerce by sea routes.

**1. Phoenicians and Greeks.**—The first people to add this development to overland commerce were the Phoenicians. From their bases on the Syrian coast they carried goods by sea to Cyprus and Rhodes and, step by step, found their way to the western Mediterranean and beyond. The original cities of Tyre and Sidon and the colonies they founded, of which Carthage became the chief,

were true commercial centres. Glassware, textiles and articles wrought in metal were exchanged for tin, copper and silver in the west. The Phoenician merchants apparently made their exchanges on the basis of goods for goods; it remained for their rivals and successors, the Greeks, to spread the use of coined money, which probably appeared in the 8th century B.C. Athens in particular introduced and maintained an excellent silver currency, which won general acceptance because it was not allowed to depreciate. Athens exported olive oil, figs, honey, pottery and small quantities of metal and textile goods. Its trade with the ports on the Black sea was an early example of dependence for essential food supplies (mainly wheat) on regular communication by sea. The fortified harbour of Piræus also attracted a considerable volume of entrepôt trade, being used by the merchants of Asia Minor and Syria in their dealings with the rest of Greece and with the countries of the west. Greek commercial enterprise was offered new opportunities when the conquests of Alexander the Great opened the way into the heart of Asia. The consequent stimulus to long-distance trade was reflected in the growth of Antioch and Alexandria as great commercial cities.

**2. Commerce of the Roman Empire.**—In the earlier phases of its history Rome took little interest in commerce. In its origins an agricultural community, it long clung to its traditions. But the series of events which led to the destruction of Carthage (146 B.C.) and the assertion of Roman supremacy over Greece necessarily revealed the possibilities of commercial development. When Augustus put an end to civil dissension and inaugurated a period of peace these possibilities were fully explored. The main currents of trade continued in the direction determined by the Greeks. To Antioch came the chief caravan routes from the east. The commodities thus secured were shipped from its port, Seleucia Pieria, Syr., to all parts of the Mediterranean. They were the traditional articles of trade—spices, drugs, silks, etc., supplying the demand of the wealthier classes.

The commerce of Alexandria, however, was of a more complicated nature. Oriental luxury goods from Arabia and India reached Egypt by way of the Red sea. Augustus took steps to protect this trade by forcing the Arabs and Ethiopians to desist from piracy and by having the navigation canals repaired. The discovery of the periodicity of the monsoon winds of the Arabian sea about the middle of the 1st century A.D. made a direct voyage to India possible and eliminated the need of calling at Arabian ports. There is much testimony to the extent of this commerce in the first two centuries. Pliny complains that the demand for eastern luxuries was so great that it caused a drain of silver from the west to pay for them. But there was another side to the trade of Alexandria. The importation of corn from Egypt was essential for the sustenance of the growing population of Rome. About 20,000,000 bu. were imported annually, part of it being produced on the emperor's domains in Egypt, but most being extracted as tribute from the province. Elaborate precautions were taken to safeguard the supply. The port at Ostia, where the corn was unloaded, was improved by Claudius. Trajan instituted regular sailings and provided granaries for storage. State supervision was thought necessary not only because the trade was vital to the existence of Rome but because of its very nature. There was no true exchange of goods between Rome and Egypt. Even at its zenith Rome was singularly unproductive; it never produced the means of paying for its imports. Little is known of the organization of commerce, as, for instance, of the respective functions of merchants and shippers; but the corn trade was not one in which private enterprise was given free play. Ships which were not part of a convoy were in danger of being attacked by pirates. Weather conditions in the Mediterranean made winter sailing perilous. With favourable winds the voyage between Alexandria and Rome could be accomplished in eight or nine days. When winds were contrary recourse had to be had to coasting from point to point and weeks could easily be consumed. It is not surprising, therefore, that the activities of the private merchant continued to centre in the provinces of the eastern Mediterranean. Some of them found means of extending their trade to the west as the Roman empire promoted the growth of cities where a demand for luxury

goods arose. But the fact that commerce had its roots in the east is proved by the fact that in most cases the merchant discovered in the west turns out to be a Greek, a Syrian or a Jew.

**3. Byzantine Empire.**—When the Roman empire in the west collapsed under the successive blows of the barbarian invasions the volume of this trade was greatly reduced. Commerce was virtually confined to the eastern Mediterranean where Constantinople enjoyed pre-eminence as the capital of the east Roman or Byzantine empire. Antioch had been sacked by the Persians in 540 and was captured by the Saracens in 638. The rising Muslim tide swept over Egypt, and Alexandria itself capitulated in 640. Constantinople, however, did not fall into the hands of a Muslim conqueror until 1453. Until then it attracted to itself the commerce between Asia and Europe. From the fall of Rome in the 5th century to the age of the crusades it was the great entrepôt of long-distance trade. Unlike Rome, Constantinople and the other cities of the Byzantine empire established a reputation for their manufactures. High-quality textile goods, leatherwork, armour, engraved and enameled metal articles of exquisite workmanship, carved ivories, mosaics and porcelain were among the exports. Corn, wax, furs, amber, salt fish, unwrought metals and raw wool were secured in exchange from the less advanced peoples. Merchants had the advantage of good money—the bezant, a gold piece which was generally acceptable. The principles of banking and the use of credit notes were known. Loans could be raised at a moderate rate of interest. Shipping was assisted by the development of insurance. It is true that from the reign of Justinian I (527–565) there was a tendency to conduct commercial policy in the fiscal interests of the empire. There were heavy duties on the import and export of certain commodities, and taxes were levied on purchases and sales. Justinian also introduced the principle of monopoly in favour of the silk industry which he took pains to set up in order that the empire might be independent of the supplies from the east which were controlled by Persia. Against these restrictions must be placed the influence of the great fairs of Constantinople and Thessalonike at which the merchants who resorted to them from all countries enjoyed great freedom of trade. Concessions were also made to alien merchants by granting them special quarters. The most-favoured of them, such as the Venetians and the Genoese, had extensive privileges; others were subject to restrictions as to the time they were allowed to stay within the empire and their business had to be conducted under supervision.

## II. THE MIDDLE AGES

**1. Italian Trading Towns.**—The heirs of Constantinople were the Italian trading towns. They had developed under the aegis of the Byzantine empire and they profited from its decline. Venice in particular rose to splendour in the middle ages. Situated amid the lagoons at the head of the Adriatic sea, it was at first a place of refuge in the troubled days of the barbarian invasions. A position could hardly have been better chosen to serve as an entrepôt through which the trade of the Levant could pass into central Europe as conditions there became more settled. The merchants of Germany had access to it across the Brenner pass, and goods could also be conveyed along the valley of the Po and by way of the St. Gotthard pass to the growing towns of the Rhineland and the Low Countries beyond. The Venetians themselves, however, operated mainly by sea routes. It was by sea that they imported oriental commodities. To make the sea route to the eastern Mediterranean secure they aimed at gaining control of the coast line and the islands. Advantage was taken of the crusades to pursue this policy. Concessions were exacted in return for shipping services. Although the Venetians were not responsible for the subsequent diversion of the fourth crusade to the capture of Constantinople itself in 1204, they took advantage of the turn of events and claimed large territorial grants. This persistence in strengthening Venice's hold in the Levant indicates the character of its trade. Year by year it was attempting to find new outlets in the west for the goods carried by caravans from the east and the products of Byzantine workshops. As Venice was pre-eminently a sea power it was natural that it would consider a sea route to the

west. From the early part of the 14th century a fleet of galleys was dispatched to the countries of the western Mediterranean, and it made its way by easy stages through the Strait of Gibraltar as far as the Low Countries. The voyage, which was usually annual, was publicly organized and controlled. The goods, however, were carried on the account of individual merchants to whom opportunity of securing space on the ships was offered by auction. Since Bruges, Belg., was then the chief mart of northwest Europe most of the cargoes were directed there; but a ship might detach itself from the fleet to call at Southampton, Sandwich or London. By this means such commodities as pepper, cloves, indigo, ginger, etc., were carried to the west at a lower cost than that of the overland route. As a return cargo the galleys took wool, hides and metals which were worked up in Italy for export to the east. Florence was the centre of a flourishing cloth industry organized on a capitalist basis, and Lucca had an important silk industry. Commerce was greatly facilitated by the improved mechanism effected by the Italians in the methods of account keeping and the organization of credit. Bankers, particularly those of Florence, had connections throughout western Europe. The commercial activities of Venice were rivaled, though not equaled, by those of Genoa and Pisa. Genoa strove not unsuccessfully for a share in the Levantine trade and contended with Pisa for the trade of north Africa and Spain.

**2. Hanseatic League.**—The fact that the Venetians found it worthwhile to make a direct sea voyage to the Low Countries shows that good markets for long-distance trade had grown up there by the 14th century. These had developed slowly from the 9th century onward as new kingdoms had arisen out of the ruins of the Roman empire. Merchants began to enjoy some measure of protection. Charles the Great, for instance, assured Offa of Mercia in 796 that any of his subjects lawfully pursuing their business in his dominions would be safeguarded against oppression. The Norsemen found their way by river routes from the Baltic to the Black sea and obtained supplies of oriental goods. Progress was slow at first. By the 11th century, however, German towns had taken the initiative and the merchants of Cologne were particularly active. The towns of north Germany entered into agreements with one another to co-operate in suppressing robbery on the roads and piracy at sea. Out of such understandings the powerful Hanseatic league ultimately emerged. It was a confederation of towns, mostly though not exclusively in Germany, formed to consult their common commercial interests. The league was in some respects no less than a great commercial state; it had its regular assemblies, its courts and its treasury, and it entered into treaty relations with foreign states. The main purpose was to gain concessions in its favour from the rulers of other countries. Such privileges it strictly confined to its members. In countries where long-distance commerce had not developed the league negotiated for factories or settlements which were at once residences and warehouses. There was a factory at Bergen, Nor., from which the trade with Iceland could be carried on, and another at Novgorod, Russia, where goods could be exchanged for Russian products. In London the league had its settlement called the Steelyard, and it long enjoyed more favourable terms than any other merchants in the payment of customs duties. Still more important was the position it occupied in Bruges where the merchants of northern Europe and the Mediterranean came into direct contact. Bruges was the chief market for English wool and Flemish cloth. The Hanseatic merchants, therefore, were chiefly engaged in exchanging the products of the northern countries—furs, salt fish, flax, timber and tar—for wool, leather, cloth and the commodities in which the Italians specialized. Under the leadership of Lübeck and Hamburg the league established a great prestige which was of first importance in the commercial development of northern Europe.

**3. Characteristics of Medieval Commerce.**—The total volume of long-distance trade in the middle ages was comparatively small. For the necessities of life most areas were self-sufficing. The goods which entered into international trade were still mainly articles of luxury for the wealthier classes. Oriental products reached western Europe chiefly through the agency of Venice and

Genoa. They were paid for to an increasing extent by the export of high quality woollens. Cloth was the first European product to be carried long distances in considerable quantities. It became worthwhile for special classes of merchants to devote all their attention to its sale. For the most part, however, merchants dealt in a variety of goods. Particular value was therefore attached to the right of retail trading, which local merchant guilds tried to monopolize by forcing outsiders to sell in bulk. The members of the Hanseatic league were extremely jealous of the privilege of retailing where they had secured it.

Medieval commerce was restricted in many directions. Transport remained expensive both by land and sea. By land only small quantities could be carried by pack horse or some such method and frequent tolls were exacted; by sea it was customary to arrange common sailings for the sake of convoy and this meant that the relative cheapness of carriage had to be set against the slowness with which the capital invested was turned over. Local organizations of merchants often succeeded in imposing serious restraints on foreigners. The custom of hosting was common, usually requiring that aliens should have the period of their sojourn in a country limited to 40 days and that they should stay with a native merchant to whom the details of their business should be revealed. Commerce also frequently suffered from regulations imposed in the fiscal interest of governments. The chief goods on which customs were paid had to pass through prescribed staple ports, and the situation and number of such ports were subject to constant change, usually for political reasons. The export of money was often forbidden because special importance was placed on the accumulation of the precious metals within the country. Sometimes alien merchants suffered from popular outcry against the nature of their trade, it being alleged that they were importing useless or harmful luxuries and exporting necessities. The catalogue of discouragements, whether natural or artificial, seems formidable. It should be remembered, however, that local and governmental restrictions were often relaxed. Reference has already been made to the privileges enjoyed by organizations of alien merchants such as the Hanseatic league. The fairs (*see* EXHIBITIONS AND FAIRS) also gave opportunity for temporary freedom of trade and were resorted to by merchants engaged in long-distance commerce. Among the most notable fairs in western Europe were those of Champagne, France, which were held at Provins, Troyes and other centres, and extended over the greater part of the year. Merchants attending them were guaranteed safe journeys and protection in their lawful enterprise. In the conduct of the fairs a common code of mercantile law was evolved to meet the problem of settling disputes between merchants of different countries without delay. The mechanism of trade was improved. Money changing had to be arranged because of the great variety of coins. From money changing, money-lending was an easy step. The inconvenience of paying debts at a distance by incurring the risk of sending money, when it was lawful to do so, or by dispatching goods which the debtor was willing to accept, was removed by the growing use of the principle of the bill of exchange.

### III. THE EARLY MODERN PERIOD

**1. From the Mediterranean to the Atlantic.**—The conquests of the Ottoman Turks in the 15th century threatened to close the routes by which oriental goods had reached the Levant. Constantinople fell into their hands in 1453, and although Venice succeeded in negotiations for the retention of its trading privileges for a time, the Christian powers looked upon the Turkish advance into Serbia, Walachia, Bosnia and Greece with apprehension. Venice itself was involved in a series of wars with the Turks in the 16th century and suffered heavily from the exhaustion of its resources and the loss of territory. The question naturally arose whether the commodities could be obtained by some other route. The pioneer work of Prince Henry of Portugal was rewarded by the rounding of the Cape of Good Hope by Bartolomeu Dias de Novais in 1488 and by Vasco da Gama's successful voyage from Lisbon to Calicut in 1498. Meanwhile Christopher Columbus, a Genoese sailor in the service of Castile, sought India by sailing west

and discovered a new world lying across his path.

These discoveries were destined to effect a revolution in commerce, but their consequences were not apparent for some time. Portugal and Spain claimed exclusive rights in the exploitation of the new routes. The English endeavoured for a time to find a northern passage to the east. As a result of Richard Chancellor's success in 1553 in reaching Archangel and on the basis of trading concessions made by the tsar of Russia an English joint-stock company—commonly called the Muscovy or Russia company—was formed. It included in the area with which it proposed to trade Armenia, Media, Hyrcania, Persia and the Caspian sea; in other words, it intended to come into contact with the trade routes of central Asia. That this was possible was demonstrated by the celebrated traveler, Anthony Jenkinson, who in 1557–59 went from Archangel to Moscow, along the Volga to the Caspian sea and then found his way to Bukhara, where he saw great numbers of Indians and Chinese buying and selling. The Russia company made good profits from its Persian voyages in the years 1566–81. As to a northwest passage the persistent endeavours of the English to find one are illustrated by the careers of Martin Frobisher, John Davis, Henry Hudson and William Baffin. But the tendency of the eastern trade to return to its old channels was still strong. An agreement was arrived at with the sultan of Turkey and an English company was formed in 1581 to carry on direct trade with the eastern Mediterranean. It was fully incorporated as the Governors and Company of Merchants of the Levant in 1592. For several years the company did fairly well, particularly by importing currants, but toward the end of the century it met with difficulties.

**2. Sea Route to India.**—Meanwhile Portugal and Spain had been endeavouring to profit from their discoveries. The Portuguese aimed at controlling for their own advantage the existing Indian trade routes to Africa, the Red sea, the Persian gulf, the Cambay ports and the Spice Islands. The centre of their power was Goa, but they had important settlements at Hormuz, Calicut and Cochin. In 1580 the crowns of Portugal and Spain were united in the person of Philip II. This meant that the Portuguese possessions were at the mercy of the enemies of Spain. The position of the Spaniards in the new world had already been challenged by English sea captains. Spain had concentrated its main attention on the silver mines of Mexico and Peru. The treasure thus obtained by forced labour was expended in Europe in buying commodities from other countries and in the conduct of wars. The treasure did not strengthen the commercial position of Spain. The one general result of its policy, indeed, was a fall in the purchasing power of money with all the social consequences of a price revolution. Francis Drake in his famous circumnavigation of the world in the years 1577–80 showed at how many points Spain could be attacked by an intrepid adventurer. He returned with a cargo of gold, silver, silk, pearls and precious stones. These were the spoils of a daring exploit but provided no foundation for trade.

In the last decade of the 16th century the English and Dutch turned their attention to the cape passage to India. Sir James Lancaster in the expedition of 1591–94 reached the Indian ocean. A Dutch voyage of 1595, commanded by Cornelius Houtman, succeeded in getting a valuable cargo of spices from Bantam. Encouraged by this example, and provoked to action by the high prices the Dutch exacted for spices, the Levant merchants in London took steps to form a new company. A charter was granted to "The Governor and Company of Merchants of London trading into the East Indies" on Dec. 31, 1600. For the first seven years the voyages of the company were directed to the Spice Islands. The trade was lucrative, but presented one serious difficulty—the ships could not take out commodities which the natives wanted. From its inception the company had been given the right to export silver, provided it did not exceed £30,000 in value in any one voyage; but this privilege exposed it to the charge that it was undermining the strength of the country. The company could not but be sensitive to this attack. When their factors at Bantam informed them that there was a good market for Indian calicoes there, they naturally explored the possibility of sending English goods to the Cambay ports, where they could be exchanged for

calicoes, which were acceptable in exchange for spices in Java. So the company sought and ultimately obtained the right to establish a factory or trading settlement at Surat. There they found that indigo could be bought at a price which yielded high profits in Europe, and it long remained one of the chief articles of direct trade between England and India. A footing was also gained in Persia where silk was obtained for export to Europe. The English company, in fact, gradually established itself on the mainland, the growing hostility of the Dutch driving it from the Spice Islands. In the later years of the 17th century the English woolen industry was complaining that the import of Indian textiles was ruining its trade; and later the use of certain Indian piece goods was prohibited in Great Britain. They were imported and offered by auction for re-export and mostly shipped to West Africa. This example shows that the costs of carriage were so reduced by the development of the direct sea route to India that fabrics cheap enough to clothe Negro slaves could enter into the trade.

**3. Rivalry of England and Holland.**—English commerce had been largely in the hands of aliens, chiefly Italians and Germans, during the middle ages. But two groups of native merchants in the course of time won recognition as distinct companies—the Merchants of the Staple, who exported wool, and the Merchant Adventurers, who sought markets for English cloth. With the growth of the woolen industry the latter became the more important of the two. Their origins are obscure, but by the 16th century they enjoyed the monopoly in the export of cloth by English subjects to the Low Countries and Germany. They came into conflict with the merchants of the Hanseatic league, and in 1578 the Germans finally lost the favourable position they had so long held in England. The Merchant Adventurers themselves had their chief seat abroad at Antwerp, which in the 16th century had succeeded to the position previously occupied by Bruges; but the political disturbances in the Low Countries drove them to seek a centre in the north and they eventually settled in Hamburg. The Hanseatic league monopoly in the Baltic was further challenged in 1579 by the formation of the Eastland company which secured concessions in Elblag at the mouth of the Vistula. The formation of all these trading companies might suggest a successful policy of promoting English commerce. That was not necessarily the fact. The companies were given exclusive rights as far as English subjects were concerned in the areas assigned to them and they were tempted to exploit this privilege for their own ends. There is good ground for contending that the expansion of trade was due to the interlopers who defied the rights of the companies and tried to break their monopoly. At any rate the 17th century witnessed many attacks on the company system because it was alleged to restrict commerce; and the case against it seemed the stronger since Dutch competition was in so many instances successful in depriving the companies of trade in their special areas.

The wealth of Holland rested primarily on the degree of organization it applied to the herring fishery, for this gave it experienced sailors and a commodity for which there was a great demand in the European markets. The fishing season was so arranged that a great fleet was kept constantly at sea and its wants supplied by other ships which brought in the herrings ready salted and packed in barrels. Situated at the mouth of great riverways, the Dutch were able to dispose of this fish on profitable terms. Amsterdam, it was said, was built on herring bones. Fishing led to an improvement in shipping and the building up of the proud position of being the chief maritime carrier in the world. Dutch towns were intimately connected by waterways and each specialized in some direction. Ships were built appropriate for the different kinds of cargoes and their parts were standardized. With a high net tonnage, and managed by a comparatively small crew, specialized ships following a regular course in quick succession could easily offer freight rates with which other countries could not compete. Writing in 1665 Sir Josiah Child gave a list of trades which the English had lost—the Russian, the Baltic, the Spanish, that of the Spice Islands and the far east, even that of Scotland and Ireland—all had fallen to the Dutch. They had, according to him, the advantages of better education, better workmanship, better commercial laws, better ship designing, and above all a better banking

system with a lower rate of interest. The English Navigation act of 1651 was designed to damage the Dutch carrying trade by requiring that, as a general rule, goods should not be imported except in English ships or ships of the country where they originated. Contemporaries supposed that this policy did irreparable harm to the Dutch, but their opinion is not supported by the evidence. The Dutch carrying trade survived with little diminution for many years; its relative decline in the 18th century was due to other causes.

**4. Mercantile System.**—"The ordinary means to increase our wealth and treasure," declared Thomas Mun in the middle of the 17th century, "is by foreign trade, wherein we must ever observe this rule—to sell more to strangers yearly than we consume of theirs in value." This meant that a government should see that the value of the commodities exported was greater than that of those imported; the difference, it was supposed, would have to be paid in treasure; i.e., coin or bullion. The means adopted to secure a favourable balance of trade in this sense constituted the so-called mercantile system (*q.v.*). The trade with foreign countries in general and each country in particular was examined to discover whether the general and particular balances were or were not favourable. If a balance was considered to be unfavourable, steps had to be taken to correct it. In France Louis XIV's minister, Jean B. Colbert, set himself to promote French commerce on these principles; he accordingly tried to restrict trade with England and Holland. English mercantilists, on the other hand, regarded trade with France as disadvantageous and it was subjected to the prohibitive tariff of 1678 until William Pitt initiated a more liberal policy in the commercial treaty of 1786. It was also found that the importation of naval stores—tar, pitch, resin and timber—from the Baltic meant that England had a permanently unfavourable balance of trade with Sweden and Russia; consequently an attempt was made to stimulate a new source of supply by offering bounties on the production of these commodities in the American colonies. In fact colonization seemed to offer to the countries of western Europe a way of escape from the supposed disadvantages of unfavourable balances of trade. The colonies might either produce the commodities which had otherwise to be imported from a foreign country, such as naval stores, or send to the mother country some staple goods, such as tobacco or sugar, which could be re-exported to foreign countries and thus give it a firmer position in their markets. It was for this reason that the English Navigation act of 1660 "enumerated" certain articles which had to be sent in the first instance to England, a list which included sugar, tobacco, indigo and ginger. The mother country was to be the entrepôt for these goods. It followed that the highest value was put upon the colonies which produced them; i.e., the West Indies, Virginia and Maryland. The New England colonies were looked upon with suspicion because they produced commodities similar to those of the mother country. There is no doubt, of course, that England would have made high profits had it been able to monopolize the new staples which were now entering into long-distance trade. For a time England supplied the European markets with sugar, but in the 18th century Dutch and French producers were able to undersell it. The aims of mercantilism had been defeated by the course of events. The revolt of the American colonies in 1776 made a serious breach in the system, and the publication of Adam Smith's *An Inquiry Into the Nature and Causes of the Wealth of Nations* (1776) supplied the classical refutation of its fallacies.

**5. Industrial Age.**—The great importance that was at that time attached to the trade in sugar and tobacco and the East India company's monopoly in tea, is an indication of the change which had come over long-distance trade. Commerce was now supplying the necessities of the many rather than the luxuries of the few. Since these necessities were only to be obtained in exchange for other goods, the increasing demand promoted industries in the trading countries. This was particularly the case in Great Britain where commercial expansion led to an industrial revolution. A country which had attempted to use colonial staples in order to become "a nation of shopkeepers" found itself converted into "the workshop of the world." Its position as a great ocean carrier, the

financial system which had been built up, the freedom of movement for persons and goods within its boundaries and the natural resources in coal and iron all contributed to this conversion. Perhaps one of the most significant results was the change in the direction of the flow of textiles. Until the end of the 18th century the trade with India had been looked upon with some disfavour because it involved considerable imports of calicoes and muslins and a comparatively small export of English woollens. The introduction of machinery in the Lancashire cotton industry completely altered the position. Raw cotton was now imported in large quantities from America and machine-made piece goods were sent to India where they were sold at such prices that the native products could not compete with them. The application of steam power to transport enormously enlarged the scope of commerce. Railways opened up the interior of the continents and so brought to the ports commodities which would not otherwise have entered into long-distance trade, or in many cases indeed would not have come into existence. The steamship reduced the length of voyages and construction in iron—and later in steel—greatly increased its carrying capacity; services were also more regular than in the old sailing days. When the Suez canal was opened in 1869 it provided a much shorter route to the east particularly suited to the steamship.

All these changes naturally reacted on commercial policy. Great Britain between 1820 and 1860 abandoned the restrictive system which had survived from the 18th century. To sell its manufactures in the markets of the world it opened its ports to the raw materials and foodstuffs which other countries could supply. It was also able to put its financial resources at the disposal of those who undertook the building of railways and other projects abroad and thereby helped to multiply the goods which entered into commerce. Railways and low ocean freights made it possible for wheat grown in the Mississippi valley to be sold in Great Britain at prices which drove British farmers to reduce arable cultivation. A rapidly growing population depended to an ever greater degree on the import of food from overseas.

#### IV. THE 20TH CENTURY

In the later decades of the 19th century the process of industrialization made rapid progress in other countries, particularly in the United States and Germany. They possessed deposits of coal and iron—the essential prerequisites in the first phase of industrialism—and became great manufacturing centres. A country cannot develop such resources on a large scale and remain independent of other countries; for the ideals of self-sufficiency and industrial development are incompatible. The reasons are obvious enough. An industrialized country is an urbanized country; the industries require raw materials and wide markets for manufactured goods and the population needs food supplies which must be sought elsewhere. So there emerged a system which was an uneasy combination of rivalry and interdependence. For while the industrial countries competed with one another in supplying nonindustrial countries with manufactured articles and in trying to gain access to the tropical products, such as rubber, which were beginning to assume importance, they also found the widest scope for the exchange of goods in the trade among themselves, because highly organized communities naturally offer the best markets for a great variety of commodities. Before World War I, for instance, Great Britain sold more to Germany than to any country except India, and bought more from Germany than from any country except the United States.

These commercial ties seemed to some to preclude the possibility of war between the great powers. This proved to be wrong. Still war revealed the fact of the real interdependence of nations. It showed that great industrial communities cannot inflict damage on one another without suffering themselves in the process and indeed endangering the whole economic structure on the preservation of which the standard of life of their dense populations ultimately depends. A world economy must necessarily mean that it is only a degree less disastrous to win a war than to lose it. The fundamental fact in the modern world is the revolution in the means of transport and communication. Before the industrial age the movement of men and goods was difficult and therefore excep-

tional; it has become easy and usual. And while modern inventions have greatly speeded up transport they have practically annihilated distance with respect to the sending of information. The sale of goods in large quantities can be effected at great distances. Where grading is possible they can be sold by description even before they have come into existence; for speculators engage to deliver goods at a given price at a future date in the expectation that they will be able to buy at a lower price when the time comes to deliver. In these and other respects the mechanism of modern commerce tends to establish a world market in certain staple commodities.

**1. Development After 1914.**—Although what once had seemed the certain approach toward universal free trade had already been interrupted and partly reversed in the last quarter of the 19th century, it was only World War I which finally destroyed these hopes, and ushered in a new period of controlled trade governed by motives not unlike those of the mercantilist period. For a time the disturbances caused by the war and its aftermath were regarded as temporary and an ultimate return to normal was expected and for a short time even seemed within reach. But as a whole the interval between World Wars I and II must appear in retrospect as a period of continued disorganization and disorientation, dominated wholly throughout its second half by the great depression. At least in Europe trade policies were governed by the new trend in internal economic policy, the increasing tendency of governments to control economic life and especially their inflationary monetary policies dictated by financial needs, while in the United States the period was marked by a return to high protection culminating in the Tariff act of 1930. An attempt to restore the international gold standard on which the relatively free flow of commerce in pre-World War I days had been based—an attempt unfortunately combined with the endeavour to bring the depreciated pound sterling back to its former value in terms of dollars—broke down in the financial crisis which in 1931 accentuated the sharp downward turn economic development had taken in 1929.

During this later part of the interwar period, under the stress of the depression, the very character of the commercial policies of the nations changed. While until then, custom tariffs had been the main obstacle to the free flow of goods, quantitative restrictions in the form of import quotas, licensing and outright prohibitions became the main instruments of commercial policy until a free trader meant someone who desired that only tariffs should be used for the control of trade. Commercial policies became increasingly subordinate to monetary policies and in particular dependent on the practices of foreign exchange control, which had become an almost universal institution. The outstanding new development of the period was a strong tendency toward bilateralism, attempts to balance the volume of trade between any two nations, with the inevitable result that the greater part of international trade which depends on triangular or multiangular relations between nations became increasingly difficult and the total volume of international trade tended to shrink even more than corresponded to the reduction of internal trade caused by the depression.

Yet the dependence not only of prosperity but of continued industrial progress on commerce remained as great as ever. It had often been argued that modern technological progress with its increasing substitution of synthetic for natural raw materials, and the growing interdependence provided by the possibility of manufacturing particular articles formerly available only from special locations, would more and more reduce the importance of commerce but this view proved unsound. Just as the industrialization of new countries such as Germany or Japan made them not only new competitors but also the best customers of the older industrial countries, so the technological developments if anything increased rather than decreased the advantages and opportunities of profitable international exchange. The tendencies toward national self-sufficiency which showed themselves during the interwar period, were everywhere the artificial results of deliberate measures of policy which came increasingly to be recognized as the main obstacles to a return of prosperity. Yet each government, aiming at short-term results and responding to the ever-changing policies of

other governments, had little possibility of extricating itself from the accumulated results of emergency measures which had a paralyzing result on trade in general. Little had been achieved to break this vicious circle when World War II intervened and, even more thoroughly than had World War I, brought to an end all international commerce of a spontaneous and undirected character.

**2. Trends After World War II.**—The state of opinion and general political conditions after World War II made a simple return to a system of free private commerce seem even more impracticable than it had been after World War I. For a time the retention of a system of state trading in many of the major staple commodities even by some of the leading commercial nations such as Great Britain threatened to force the adoption of similar practices on nations who would have preferred to leave international commerce to free enterprise. But the reaction against the tendency to increasing state control which set in a few years after the war led to new efforts to reduce trade barriers and to free the flow of private commerce. If anything had been demonstrated by the largely abortive efforts in this direction made during the period between the wars it was that neither the independent efforts of individual states nor bilateral negotiations carried on between two states at a time offered much hope in this respect. The whole system of regulations and commercial treaties had grown far too complex, and the interdependence of the obligations entered and concessions made by particular nations toward each other far too great for any prospect of rapid improvement by the traditional method.

The new approach was based on an endeavour to bind as many nations as possible by a single general agreement to reduce or abolish all quantitative restrictions of trade, especially all those of a discriminatory character; to aim at a progressive lowering of tariffs; and to set up for that purpose a permanent machinery which would make it possible for the different nations to negotiate renewals of their commercial treaties at periodic meetings held at one place and one time. As a result of these endeavours in 1947 and 1948 a General Agreement on Tariffs and Trade (G.A.T.T.) was concluded. Formed at first by 23 nations on a temporary basis, G.A.T.T. later expanded and was renewed and in a series of meetings achieved not inconsiderable success toward a general reduction of international trade barriers. Assisted by an unusually long period of high prosperity the volume of international commerce in consequence rapidly recovered and far exceeded the pre-war volume.

And although for a time after the war it seemed as if political uncertainty and the dependence on the U.S. foreign-aid program would be the source of lasting instability, the prospects of a gradual establishment of a new and fairly stable pattern of trade adapted to the new conditions steadily improved.

**COMMERCIAL COURT**, in England, a court presided over by a single judge of the queen's bench division, for the trial, as expeditiously as possible, of commercial cases. It is not a distinct court or division or branch of the high court of justice and is not regulated by any special rules of court made by the rules committee. It originated in a notice issued by the judges of the queen's bench division in Feb. 1895, the provisions of which represent only "a practice agreed on by the judges, who have the right to deal by convention among themselves with this mode of disposing of the

business in their courts" (per Lord Esher in *Barry v. Peruvian Corporation*, 1896, 1 Q.B. p. 209). The court's chief feature is the speed with which causes assigned to the Commercial list can be concluded. It is for the judge in charge of the list to decide, on application from one of the parties, whether an action is to be included in the Commercial list or not. The work of the commercial court decreased in volume after World War II, partly because of the increased use of commercial arbitration for the settlement of trade disputes. (W. T. Ws.)

**COMMERCIAL LAW:** see **BUSINESS LAW**.

**COMMERCIAL PAPER**, a term used broadly to describe the many kinds of short-term negotiable instruments for the payment of money, such as notes, checks, bills of exchange and the like. In the United States the term also applies, in a strict sense, to negotiable notes, with maturities usually of from four months to one year, which are issued by corporations with good to excellent credit ratings in even denominations of, say, \$5,000 or \$10,000 and sold through brokers to the public, i.e., principally to insurance companies, banks and other corporations with idle short-term funds to invest. These notes are referred to as prime commercial paper when interest rates are reported in the financial pages, and the aggregate volume outstanding is an index of business activity.

It is necessary to distinguish commercial paper from investment paper (*q.v.*), or, more commonly speaking, from corporate or investment securities. Both are money instruments, issued generally in negotiable form; both may be either for a short or a long term; both may be issued in even denominations and be secured or not by collateral; both are in some measure a medium of investment. But while it is difficult to draw a sharp line, as for example, between a particular promissory note and a debenture, the business community regards the two classes of paper as having quite different qualities and as serving different purposes. In general, bonds, debentures, share certificates, collateral trust notes, equipment trust certificates and so on are regarded as investment securities.

**Bill of Exchange.**—The earliest and most complex form of commercial paper is the bill of exchange or draft. It has been defined in England as an unconditional order in writing addressed by one person to another, signed by the person giving it (the drawer) and requiring the person to whom it is addressed (the drawee) to pay on demand or at a fixed or determinable future time a certain sum of money to, or to the order of, a specified person (the payee) or to bearer. In the United States the definition is the same, except that there an instrument may only be made payable "to order or to bearer." If the drawee assents to the order and accepts the bill, which is done by signing his name (or his name with the word "accepted") across the face of the paper, he is called an acceptor. The person to whom a bill is transferred by endorsement is called the endorsee. Any person in possession of a bill, whether as payee, endorsee or bearer, is termed a holder, and if he is a bona fide purchaser, a holder in due course.

The bill of exchange probably grew out of so simple a matter as the letter of a seller in one country, addressed to a buyer in another, by which the buyer was advised of the shipment of goods and was requested to pay the price—or a given sum of money—to a person named or to the bearer of the letter. In time the request, or order to pay, became separated from the letter and, as Marius says in his *Advice Concerning Bills of Exchange*, published in 1651, emerged as a mere slip of paper "not more than three or four fingers wide." The letter to the buyer has continued in use, mainly in foreign commerce, as an advice of drawing.

The significant thing is that the bill thus became a separate instrument for the payment of money, to be dealt with as such quite apart from any underlying transaction. According to Sir W. S. Holdsworth, something very like the modern instrument, capable of being transferred from hand to hand, was in use among the Arabs by the 8th century A.D. But the bill in its present form first attained wide use during the 13th and 14th centuries among the Lombards—merchants, traders and money-changers of northern Italy—who carried on a considerable foreign commerce. Probably the English merchant of the time was also well acquainted with

the bill; the first reported case, though, is that of *Martin v. Boure*, decided by the exchequer chamber in 1603.

During the 17th century the bill became widely used in domestic or inland transactions, first by merchants but soon by everyone. In fact the case of *Burton v. Davey*, decided by the court of the staple in 1437, shows that, much earlier, there was some domestic use of wordy instruments comparable to bills. As in foreign commerce, the bill afforded a needed means of settling accounts quickly and without the risk and trouble of using currency. Moreover, the common-law courts, by recourse to the "law merchant" (the mercantile law previously administered in the courts of the fair), were able to give rulings favourable to its general use. Thus, in *Chat v. Edgar*, 1663, the drawer was put under an obligation (the drawee having refused payment) to pay a payee who had taken the bill in course of trade, although the drawer had received no consideration for his signing. This was an early authority for the point, which has long since become a settled attribute of negotiability, that fraud, nondelivery and other personal defenses among prior parties are cut off upon negotiation to a bona fide purchaser.

There appears to have been little early practice to draw bills payable to bearer; in fact Marius had warned (*Advice*, p. 13), "Never make your bills of exchange payable to such an one (naming his name) or to the bearer hereof, which is very dangerous. . . ." But at sometime early in the 17th century it became usual to make bills payable to order, or to so-and-so or assigns. This was a change of great significance, for, prior to that, while a drawer might sell his bill to a remitter who in turn could deliver it to the payee, as happened in *Chat v. Edgar*, that was the end of the journey. By making the paper transferable by endorsement, however, it could be used in many successive transactions, while at the same time each holder, under a special endorsement to himself, was protected against loss in that no rights could be acquired to the paper except through his further endorsement. Bills, of course, like other commercial paper, were and still are made payable to bearer on occasion.

The courts had difficulty assimilating the merchant's endorsement. In the first place, what was his contract, since he had simply signed his name on the back of the paper with the words "pay to so-and-so"? This was solved fairly soon by assuming that the endorser had really drawn a new bill on the drawee, payable to order of the endorsee. Thus if the bill was not paid upon due presentment, and proper notice was given the endorser, he could be made to pay as a drawer. It was more difficult to state the rights of the endorsee against prior parties. On the face of it the transaction looked like an assignment (*q.v.*), and the common law had long held that a chose in action (intangible personal property, as a debt or other obligation owed to the assignor) could not be assigned. But this, too, was solved in time, for it was possible to say—since the bill was payable to order or to bearer—that the endorsee really was a party to the acceptor's contract. Also this made it easier to free the endorsee from defenses good between prior parties; he was not an assignee in the same situation as his assignor, but the holder of an independent contract.

The bill or, for that matter, any piece of commercial paper is thus a bundle of separate but related contracts. When the drawee accepts a bill, one more contract is added; the acceptor thereby obligates himself to pay the bill according to its tenor or, if his acceptance is qualified, according to the tenor of his acceptance. Like the maker of a note, the acceptor is described as a primary party, and in general no presentment for payment is necessary in order to hold him liable. But presentment and notice of dishonour (of nonpayment or nonacceptance) are necessary, unless such proceedings have been waived, in order to charge secondary parties, *i.e.*, the drawer and any endorsers. When such steps are taken, however, a holder may sue any or all prior parties, in such order as he may see fit, until recovery is had. An endorser may qualify his contract by signing "without recourse," in which case he will be liable, if at all, for breach of warranty, irrespective of presentment or notice of dishonour.

The foreign bill of exchange is one of the most cosmopolitan of instruments. By definition it must be drawn in one country or

in one state of the United States on a drawee in another country or state; but in the course of its journey prior to payment it may well be endorsed in two or three others. Several systems of law, therefore, may be called into play to construe the contracts of the parties. Also different currencies may be involved. Thus, if an endorser is sued in the United States upon a bill drawn, say, in Australia in pounds sterling, the dollar value of the pounds must be determined before judgment can be given. The measure is the buying rate of exchange for sight drafts (those payable on demand) at the place of payment on the day of breach.

Protest is necessary to charge secondary parties on a foreign bill. The holder, upon dishonour, must hand the bill over to a notary public who re-presents it and, if it is again dishonoured, draws up an affidavit stating the facts. This practice serves two purposes: it gives needed assurance to secondary parties that a real effort was made to effect payment; it also supplies necessary evidence, for the notary's certificate or affidavit is admissible in most places as prima facie proof of the matters stated in it. Protest is not required to charge secondary parties on other commercial paper, but it is nevertheless widely used when it is thought that suit may become necessary.

Due to uncertainty of the mails, a practice developed very early to draw bills of exchange in sets, as bills of lading are drawn, one part to go forward by one mail, a second by the next and the third or other parts perhaps to be retained. While this practice adds further complication, it has resulted in little litigation. In concept, the several parts represent but a single bill; successive purchasers of different parts have title to the bill according to which first acquired a part; payment to the holder of any part discharges the drawee on the bill. The case of *Lloyd v. Sigourney*, 1829, shows that the practice may also have other advantages. There the master of a vessel, upon releasing a cargo to a buyer, took payment in a bill on London, one part of which he sent, unendorsed, to agents there to obtain acceptance; another, endorsed, he sent to his principal in the United States; the third he retained. Thus, since the endorsed part carried title, the principal was given control of an accepted bill at an earlier stage in the transaction than might otherwise have been possible.

The following is an ordinary form of foreign bill of exchange, drawn in a set of two, and made payable at a future time:

\$1,000.

Chicago, Ill.  
Jan. 1, 1960

Three months after date pay this FIRST of exchange (Second being unpaid) to the order of Mr. J. Jones the sum of one thousand dollars for value received.

Brown & Co.

To: Messrs. Smith & Sons  
Liverpool, England

A bill of exchange is payable on demand when it is expressed to be payable on demand or at sight. In calculating the maturity of bills payable at a future time, it is required in some countries that three days, called days of grace, be added to the nominal due date. Thus, if a bill payable one month after sight is accepted on Jan. 1, it is really payable on Feb. 4, not Feb. 1. So, also, when a bill or other instrument falls due on a holiday or a Saturday, there are a variety of legal provisions to determine whether it must be paid then, on the day before or on the next business day. In the U.S., days of grace have been abolished in most states.

**Acceptances.**—The accepted bill, like the promissory note, is primarily a credit instrument. When goods are shipped and the bills of lading are sent forward with a draft or bill of exchange drawn on the buyer at, say, 90 days after sight, it is customary to release the shipping documents upon acceptance of the draft. The buyer thus has 90 days in which to dispose of the goods and to obtain the funds to meet his acceptance when it matures. This is known as a self-liquidating transaction. In England, acceptances arising from such transactions enjoy an excellent credit standing and are traded in by bill brokers, much as notes are sold in the U.S. on the commercial paper market.

There never has been an extensive bill market in the U.S. Sales

of finished goods by manufacturer to dealer have traditionally been carried on open account. And, while the bill is used extensively in the sale of raw materials, the usual course is for the seller to take his bill to his banker, either for discount or to be handled on a collection basis. Thus, when early in the 20th century the federal reserve system sought to promote a bill market by the introduction of a draft called the trade acceptance, it met with only partial success. The trade acceptance is an ordinary draft carrying the legend: "The obligation of the acceptor hereof arises out of the purchase of goods from the drawer." Partly to encourage the use of such paper, which has an excellent credit standing, the federal reserve banks will rediscount it at favourable rates.

The banker's acceptance arises typically in an export or import transaction. For many years in England, and since World War I in the U.S., it has been customary for buyers to provide their foreign sellers with a banker's commercial credit. Thus the seller, as beneficiary of the credit, draws his drafts upon the buyer's bank rather than on the buyer, and the documents are released to the bank upon acceptance, to be thereafter turned over to the buyer upon trust receipt or as may be arranged. Such acceptances have the highest commercial credit rating, but are more likely to be held to maturity by a bank than to be sold on the bill market. In the U.S. a bank's promise in writing to accept a draft to be drawn upon it may be binding, *i.e.*, irrevocable, as a virtual acceptance; in England, while such acceptances are not recognized, much the same result was reached in *Re Agra and Mastermans Bank*, 1867, on other principles. Under the Federal Reserve act, trade acceptances and other eligible commercial paper, together with gold certificates in a specified ratio, may be transferred to the reserve board as a basis for the issuance of new federal reserve notes.

**Promissory Note.**—The promissory note, like the inland bill, came into general use in England in its modern form during the 17th century. It is not altogether clear what its precursors were, but Gerard Malynes, in his *Lex mercatoria*, 1686, describes a "bill obligatory," which, though it was phrased like a bond ("I, A. B., Merchant of Amsterdam do acknowledge by these presents to be truly indebted to the honest C. D., English Merchant dwelling at Middleborough, in the summ of," etc.), was nevertheless made payable to "the said C. D. (or the bringer hereof)." There is evidence, moreover, not only that such instruments were in use during the 14th and 15th centuries but that they were transferred from hand to hand. If these were early forms of the note, a considerable change in wording, and probably in concept, was to take place before the clean form, which Judge Gibson once described as "a courier without luggage," evolved.

The following is a typical form of interest-bearing promissory note payable at a bank:

\$1,000, Jan. 1, 1960

One year after date I promise to pay to Chas. Dawes, or order, one thousand dollars, with interest at 6%, value received.

Payable at the  
First Bank of New York

Abe Blum

The note differs from the bill mainly in that it carries only a single obligation, the promise of the maker. This has given rise to the phrase, single-name paper, to distinguish the note from the accepted bill, which in turn is called two-name or double-name paper since the payee may have recourse against both drawer and acceptor. But this is a loose distinction at best, for additional names may easily be added to a note, either as comaker or endorser, and whether for accommodation or as borrower. Moreover, since a bill may be drawn to the order of the drawer, it likewise may be held as single-name paper. Most continental countries customarily do not use the note, but make the bill serve both as a means of collection and remittance in goods transactions and as an instrument of debt for money borrowed. That is, the lender may simply draw on the borrower and hold the latter's accept-

ance to maturity, as a lender would hold a note in Anglo-American practice.

By the end of the 17th century the legal standing of the note was still uncertain. In *Clerke v. Martin*, 1702, it was urged that a payee might recover from the maker as upon a specialty, *i.e.*, an obligation under seal, thus cutting off the defense that there was no consideration or benefit to the maker, but Lord Holt strongly opposed the action and said that the note in question could not be a bill of exchange. The result of the case was correct enough since even a foreign bill is not a specialty; but when, in *Buller v. Crips*, 1704, Lord Holt used the same reasoning to subject an endorsee to defenses between maker and payee, for otherwise "it would empower one to assign that to another which he could not have himself," there was a considerable outcry. Parliament soon passed the Statute of Anne, 1704, to put promissory notes, and inland bills as well, on the same footing with foreign bills. This statute had great influence in shaping the early law in the U.S.

Lord Holt said, incidentally, that notes were "only an invention of the goldsmiths in Lombard-Street." While this is dubious history, except in the sense that they may well have been responsible for stripping away much verbiage from the bill obligatory, it is true that goldsmiths' notes—soon to be called bank notes—were in general use at the time. A half-century later, Lord Mansfield, in *Miller v. Race*, 1758, held that an innkeeper, who had taken a stolen bank note in the usual course of business, was to be given good title, much as if he had taken money. This was a decision of great importance. In the ensuing years it became a settled attribute of the concept of negotiability, applicable alike to bills of exchange and other forms of commercial paper.

The practice of making paper "payable at" a bank is not confined to notes, for acceptances likewise are so domiciled. In England the clause was held from the first to constitute an order on the banker to pay. In the United States the older commercial states adopted the same rule, but in a few states—less impressed at the time with commercial usage—an opposite rule was adopted; thus an instrument was made payable at a bank, they said, in order to fix the place where presentment should be made to charge endorers. Moreover, even in the majority states, since no presentment is ordinarily necessary to charge the maker or acceptor, it is held, contrary to the rule with respect to checks, that insolvency of the bank of payment is at the risk of the maker or acceptor, even though the holder was very dilatory. The deposit, or cover, as it is called, thus constitutes no more than a tender or offer of payment.

The note has changed substantially, both in form and use, during the 20th century. Many clauses have been added: to authorize the sale of collateral; to permit acceleration of payment in event of default; to provide for confession of judgment (judgment against debtor without a trial); to waive presentment; to permit extensions of time; to pay attorneys' fees. The clean form is still used, but these and other clauses have become commonplace in collateral notes prepared by banks for their customers. They are also used in the notes given in installment-sales transactions, amounting in the aggregate to billions of dollars. Moreover, the old "open account" practice has been breaking up. First, it became respectable for the manufacturer or dealer to make a bare assignment of the account receivable, either to a bank or finance company, but increasingly the debtor, or buyer, has also been asked to sign a long-form note. These developments have raised many questions concerning negotiability.

**Checks.**—The check came into use in England during the latter half of the 17th century. Childs bank has a check drawn upon it in the following terms:

Bolton, 4th March, 1684, At sight hereof pray pay unto Charles Duncombe, Esq. or order, the Sum of four hundred pounds, and place it to the account of

Your assured friend  
Winchester

Thus the check is simply a bill of exchange drawn on a bank payable on demand, and it has long been so defined. But it took many years to acquire this status, in fact to acquire a name. There are early references to it as a "drawn-note" or a "bill." And in *Grant*

*v. Vaughn*, 1764, Lord Mansfield used the terms "cash-note" or "note," possibly to make it easier to apply the law of *Miller v. Race*, mentioned above, relating to bank notes. But by the end of the century the word "check" had come into general use, though in England toward the middle of the 19th century the spelling was changed to "cheque."

Since the check could be regarded as a simple direction by a depositor to his banker, there was doubt whether it was a negotiable instrument. The drawer could stop payment; the bank could be held liable for slander of credit; the drawer was under a special duty to prepare his checks with care. These were incidents of the bank-depositor relationship, and not necessarily inconsistent with negotiability. In England, however, it was seriously argued—as late as *Keene v. Beard*, 1860, but without success, that a holder could not recover against a prior endorser, as upon a negotiable bill. In the U.S. the courts ruled in the early 1800s that the check is a bill, with only one important difference: the drawer is not to be fully discharged upon a failure of the holder to make timely presentment, as in the case of a time bill, but only to the extent of his loss.

Also, the certification of a check by a bank was held in *Willets v. Phoenix Bank*, 1853, to obligate the bank as upon the acceptance of a bill. It is reported that by 1870 the average circulation of certified checks in New York was not less than \$100,000,000 daily. Brokers and others receiving large payments by check, and not wishing unnecessarily to assume the risk of a drawer's continued solvency, simply presented the checks for certification. While this had the effect of discharging the drawer, the holder obtained the obligation of the bank in negotiable form, and the check, so certified, could readily be used in further transactions. When a check is certified for the drawer, he continues to be liable as a secondary party. English banks have never adopted the practice of certifying checks, and it is likewise unknown on the continent.

The importance of the check not only as a convenient means of making payments but as a part of the currency system is hard to overestimate. Banking, in the modern sense, began in the latter half of the 17th century when, in legal concept, the goldsmith became a "debtor" rather than a "bailee." But the goldsmith, in his new role as banker, became much more than a mere lender of money, his own and that of his depositors. He had discovered that by keeping only a percentage of his customers' deposits in the till, in currency, he could make loans which aggregated twice or more the amount of all cash deposits. That is, he loaned not money, but credit, at interest. And the instrument which made this possible was the goldsmith's note or bank note. So long as he was free to issue these and they were accepted in the market place in lieu of cash, his banking system worked.

The check achieved prominence as the bank note came under strict governmental regulation. In the U.S., after a long chaotic experience with notes issued by state banks, such notes were legislated out of existence. In their place the national banks were authorized to issue notes, but only when backed dollar for dollar with specified security. The banks, however, had already found that the check would serve their purposes much as had the bank note. In short, they were free to loan their credit to their customers, keeping only so much money on hand as experience had shown to be necessary to meet payments. Since loans to customers were invariably carried as deposit liabilities, available by check, it followed that the check in a very real sense represented a sort of currency and, moreover, a kind which could be expanded or not, more or less as business or banking considerations demanded. But government here too has intervened and, through a system of required reserves, has asserted control over the mechanism.

The clearinghouse (*q.v.*) as first established by London bankers, greatly facilitated the check system. At the start it was merely a device to permit bank clerks to meet together at some central place, such as a coffeehouse, to exchange checks drawn on their banks. But by 1773 it became the practice also to set off one batch of checks against another and to make a provisional settlement at once. Not only did this save time but it obviated the risk of using currency; the few not-good items could be returned later. Moreover, the banker must have noted that it made the least pos-

sible drain on his cash needed for counter payments. In the U.S., the federal reserve system extended the practice to the clearing of items between member banks in different cities, each member's reserve account being credited or debited as the case might be. Thus, it was possible to speed up collections still further and to reduce what the banker calls "float."

In England the early stamp tax upon checks adversely affected the development of the system there; from 1791 until 1853 (when the tax was reduced to one penny), "order" checks were virtually driven out of use. Forced to use "bearer" checks, drawers and holders contrived a system of crossing—two transverse lines across the check face, usually with "& Co." written between—which required the drawee to pay only to a banker. Thus if a check were stolen from the mails, some protection was afforded since the thief, or bearer, would have to make arrangements with a banker for collection; he could not simply demand cash from the drawee at the window. When it became apparent, in 1853, that "order" checks would soon displace "bearer" checks and would be issued in great numbers, the banker got worried, for he did not like the prospect of having to take losses should payments be made upon forged endorsements. A provision was accordingly inserted in the Stamp act, s. 19, which exempted banks from liability. Subsequent enactments have extended the exemption. Accordingly, the crossing device, for what little protection it affords, is securely fastened on English practice.

The crossed check is not used in the U.S. From the first, checks were issued to order, not often to bearer, and hence drawer and holder have always been protected by the rule that only an authorized endorsement will pass title. Moreover, by the time of the *Canal Bank* case, 1841, the right of the drawee to recover from anyone collecting paper through a forged endorsement was clearly established. Since then, by use of the "prior endorsements guaranteed" stamp, recourse has been carried back through agent collecting banks. Thus if a check is stolen from the mails and the holder's endorsement is forged, the ultimate loss falls on the person who took the item from the thief, not on the innocent loser, as in England. The result is that most payments are made by check; business and personal checks alike are customarily sent by mail, uninsured, to any part of the country and with relative safety. As one index of general use, clearings in Chicago alone at the middle of the 20th century were on the order of \$1,000,000,000 a week.

Banks in the U.S., as elsewhere, sell their customers (at a small fee) different forms of checks or drafts for special uses. Thus a cashier's check, so-called, may be purchased to make a local payment of importance. As its name implies, the cashier's check is simply an order by a cashier upon his own bank. Bank drafts are often purchased to make payments in other cities, and they (or a cable transfer) are used almost exclusively when foreign remittances are made. The bank draft is indistinguishable from a check except that it is drawn by a bank rather than by an individual; both are drawn upon a bank and are payable on demand. A third type is the traveler's check, which may take the form of a cashier's check but is distinctive in that two spaces are provided so that the customer may sign at the time of purchase and again when cashing the check, as an aid to identification. (See also CHECK.)

**Uniformity.**—The Bills of Exchange act, drafted by Sir M. D. Chalmers, was adopted by parliament in 1882. Essentially it was a work of codification, designed to state in an orderly fashion, without innovation—except interstitially—the law of bills, notes and checks as found in the court decisions and the fragmentary legislation of the previous two or three centuries. The result was admirable; stated in simple language and in short separate propositions, the act was readily understandable by lawyer, banker or anyone concerned and has brought substantial uniformity throughout the British Commonwealth.

In the U.S., in 1896, the newly constituted commissioners on uniform state laws appointed John J. Crawford, of the New York bar, to draft similar legislation to be submitted to the several states for adoption. Crawford's draft, the Negotiable Instruments law (N.I.L.), was patterned closely upon the English act both in style and wording. In large measure the law of the two statutes is the same, as Crawford made changes only where the course of

development in the U.S. had clearly taken a different direction. But the N.I.L., unlike the English act, had to pass in 50 different legislatures in order to achieve uniformity, and not all of these were happy to see the special rules which had grown up in their states changed. Nonetheless, in the years 1897-99 the N.I.L. was adopted in 15 states; since then it has been adopted in all, though with some changes in text. By and large, the N.I.L. also has been an excellent statute.

One significant departure from the English act was made. The N.I.L., as its name implies, was not restricted to the law of bills, notes and checks but was drafted to admit any instrument, then in use or to be developed later, which could meet the several tests stated. Thus coupons, travelers checks, certificates of deposit, debentures and even most bonds were negotiable within the act. But the act also had a limiting effect. In *Manhattan Co. v. Morgan*, 1926, it was urged that interim certificates for bonds-to-be-issued should be treated as negotiable. They clearly did not satisfy the N.I.L. test since, for one thing, they were not payable in money. And Judge Cardozo held that the words of the statute, "An instrument to be negotiable must conform . . .," also made it impossible for the court to look to the custom of the financial community to discover negotiability, as the English court had done in *Goodwin v. Roberts*, 1875.

There were more serious difficulties; for special legislation could be provided for interim certificates, as for other investment paper. The growing penchant on the part of many legislatures to amend the statute in one way or another could not be met so easily. Some of these amendments were useful; most were hastily drafted; but whatever the case, their effect was to destroy uniformity. Equally troublesome was the considerable contrariety among court decisions. Even when construing identical texts, there have been many divergent holdings, and with respect to important sections of the statute. If it were possible to take these cases before a single court of appeal, as in England, such conflicts could be resolved. But in *Erie R.R. v. Tompkins*, 1938, the U.S. supreme court abandoned a jurisdiction it had exercised since *Swift v. Tyson*, 1842, by which it applied a single law in commercial matters.

The next step was the preparation of the Uniform Commercial code (1952), by the commissioners on uniform state laws and the American Law Institute, under the direction of Karl N. Llewellyn, chief reporter. Art. 3 of the code, which deals with commercial paper, solves the problem posed by the *Manhattan Co.* case, by providing that "any writing to be a negotiable instrument within this article must. . . ." Thus the code does not block court recognition of new forms of paper. Secondly, a new statute, art. 8, was proposed for investment securities. The result has been to preserve much of the clarity of the N.I.L. and, at the same time, to provide a uniform text covering some of the special legislation and resolving most of the conflicting decisions of the preceding half century. The code has been adopted in Pennsylvania, Massachusetts, Illinois and several other states.

But art. 3 also will not achieve uniformity unless it is well construed. Many courts, with a similar text before them, have abandoned the sense of direction and purpose which guided the earlier judges, as if codification and the common-law tradition were completely hostile to each other. Thus in *Jones v. Warring and Gillow*, 1926, the house of lords declared that a payee of a check (taken in good faith from a remitter) could not be a holder in due course. It reached this result, by no means a necessary one, by disregarding the fact that, at least since *Chat v. Edgar*, 1663, the courts, in the absence of statute, had held that it was essential to trade that payees should be given protection in that situation. The same construction, if applied to a bill, would overturn the long-established rule that a payee's rights are not to be subject to defenses between drawer and acceptor. The code deals with the problem—for there have been many equally troublesome decisions in the U.S.—by stating that a payee "may" be a holder in due course.

The law pertaining to bills of exchange in non-English speaking countries is similar in many respects to Anglo-American law. Since both derive from a common source, the early trade between

merchants of different countries, this was to be expected. But legislation came much earlier on the continent; French law, for example, was codified in the 17th century by the "ordonnance de 1673." In England, as we have seen, it was during the next two centuries that the courts, on a case-by-case basis, wrote much of the law which was codified in the Bills of Exchange act of 1882. Necessarily, there are differences not only in text but in the way the law is regarded in the two systems. The continental lawyer and commentator tend to reason mainly from concept, the Anglo-American lawyer and writer from the economic or business purposes which the instrument was designed to serve.

The Geneva conferences of 1930 and 1931 (the first session related to bills of exchange and notes, the second to checks) made considerable progress toward unifying the law of the commercial world outside the Anglo-American system. Thirty-one countries were represented at the first session and 30 at the second, with the U.S. as an observer at each. Twenty or more countries promptly signed each of the conference conventions. Moreover, some progress was made toward bringing continental and Anglo-American law into closer alignment. The most serious obstacle to a complete rapprochement is the Anglo-American rule that no title may be had through a forged endorsement. Continental countries, following a concept of full negotiability to its logical end, protect the good-faith purchaser, which ultimately forces the person whose name is forged to seek redress from the forger rather than to put that burden on the person who dealt with him. This difference may contribute to the fact that commercial paper is less extensively used on the continent than in Anglo-American countries.

Early in the 18th century Jeremy Bentham was an outspoken advocate of codification. But his main reason, that the courts should apply law and not make it, ran counter to a long tradition to the contrary. It would have better served his cause, perhaps, if he had stressed the need for uniformity, at least in the commercial paper field, and so have enlisted the business community in his support. The U.S. experience has shown that, so long as the spirit of free legislative enterprise persists, codification will not result in undue crystallization of the law. (R. T. S.)

**COMMERCIAL TREATIES.** A commercial treaty is an international agreement on trade and related matters. In modern usage the related matters have included not only those on shipping but also many subjects having to do with the status and rights of persons. In its broadest sense, the term commercial treaty might apply to any of a number of different types of arrangements between governments, including even a simple agreement that trade might go on between the parties. Used in a more technical sense, as here, the term denotes an arrangement that applies to some things besides exports and imports, and is, therefore, more than a mere tariff treaty or trade agreement. In the constitutional sense, it is a formal agreement requiring for its legal effectiveness approval by such processes as the national constitutional plan prescribes.

Traditionally bilateral in form, a general commercial treaty (which has often been referred to as a treaty of friendship, commerce and navigation) has commonly included as establishment provisions the principles or rules which apply to nationals of one country who reside in another country's territory and who carry on commercial or other activities there. Protection of these persons against discriminatory treatment in such matters as property, taxation, access to courts and basic human rights, has been an objective of this type of treaty. Since no state would be likely to allow resident aliens to have all the rights and privileges which its own citizens have, it has not been uncommon for commercial treaties

to contain specific exceptions clauses in order to keep the treaty commitments in line with policies of the respective signatory states.

Commitments on trade and on treatment of persons have not appeared exclusively in commercial treaties. They have sometimes appeared, for example, in treaties of peace or in arrangements for the transfer of territory, to be applicable either indefinitely or pending the conclusion of full-length commercial treaties between the states concerned.

**Scope.**—While stating long-recognized principles to apply to exports and imports and to vessels, commercial treaties have varied considerably in their establishment clauses. Some of these clauses have touched on matters on which there were applicable rules of public (customary) international law, such as the general protection of admitted aliens. Others have related to matters on which there have been international agreements in multilateral form, as on patents or foreign-exchange control. Still others have been on matters which lie clearly within the field of national state policy, such as the permitting of aliens to acquire real property (land or buildings, etc.), or to carry on mining operations or to organize (or invest in) corporations. Navigation clauses in commercial treaties have commonly provided rules on matters not covered by more general international law, such as provision of pilots for foreign vessels, or the basis on which vessels of one party state may engage in the coastwise trade of the other party state.

As compared with what in the strict sense of the term are called trade agreements, commercial treaties ordinarily contain no schedules of tariff reductions or "bindings" (which are characteristic features of trade agreements), and are designed to be longer-term instruments. The general commercial treaty which Great Britain concluded with the United States in 1815 was still in effect in the 1960s.

The contents of commercial treaties tend to be affected not only by changing methods of doing business across national frontiers but also by changing ideas concerning state functions, the legality of war, and means of preserving the general peace. For states having a monopoly of their export trade as in the U.S.S.R., the effect upon their commercial treaty making has been obvious; when state trading has not proceeded to this extent, but states have engaged directly in some commercial activity as in the case of a number of European countries by the mid-20th century, there has been some effort through the provisions of commercial treaties to provide some fair basis of competition between government agencies engaged in business and private foreign traders. With respect to war and neutrality, many commercial treaties of the early 19th century included detailed provisions on contraband of war, and some indicated the parties' position on the principle of "free ships, free goods." After 1920 there was reflected in various treaties the parties' resolve to keep these bilateral agreements from conflicting with duties which the states concerned had accepted as members of international organizations designed to safeguard the peace.

**Developments Prior to 1860.**—In ancient times there were many instances of treaty arrangements which regulated foreign intercourse. The texts are extant of provisions on commerce and navigation which Carthage concluded with Rome in 509 B.C. and again in 347 B.C. Aristotle mentions that peoples were connected by commercial treaties, and other classical writers refer to such arrangements. Under Roman imperial rule, laws or usages acquiring the force of law provided regulation. With the contraction of the empire and the weakening of the imperial authority, there was again need for some kind of international agreements. Edward Gibbon cites treaties in force at Constantinople in the 10th century for protection of "the person, effects and privileges of the Russian merchant."

In western Europe, commercial intercourse, trade and navigation went on, at first tacitly by usage derived from Roman times or under permission which rulers gave to foreign merchants who resorted to their courts. Later, formal documents (such as royal letters, charters, laws and other instruments having legal force and effect) provided some security for the trader. In the history

of English commercial relations, the letter of Charlemagne in 796, the Brabant charter of 1305, and the Russian ukase of 1569 are illustrative. Medieval truces or treaties of peace sometimes contained clauses permitting in general terms the renewal of personal communication and commercial relations which had gone on before the hostilities. These arrangements were precarious, sometimes not continuing beyond the lifetime of the contracting rulers.

The practice of city states in Italy provided some precedents for later treaty making in this general field. Such well-organized communities as Genoa, Pisa and Venice were in keen rivalry. Conditions prevailing in foreign territories with which these cities had dealings made it desirable to have formal agreements for the greater security of commerce and navigation. The convention which Pisa concluded with the sultan Saladin in 1173 affords illustration of such arrangements effected in the 12th century. Greater definiteness and security were presumably obtained under such agreements than would have been assured under mere usage or under grants from foreign rulers, and the practice of utilizing formal undertakings to provide for security of traders came to be general in Europe. In western Europe, a treaty of accord and alliance which Brabant concluded with Cologne in 1251 contained provisions illustrative of the growing practice. The first agreements with comparable provisions which the Hanse towns made with foreign entities were arrangements made by guilds of merchants, rather than by public authorities acting as governing bodies. For a considerable period the treaty system did not entirely supersede conditions under which commercial intercourse depended upon the foreign trader's having permission from political authorities.

England's earliest commercial treaty (with Norway, 1217) provided that merchants and men of each signatory country might freely and without impediment visit the territory of the other party. In the course of the next two centuries England made treaties of this general type with Flanders, Portugal, Baltic cities, Biscay and Castile, Burgundy, France and Florence. By the 17th century the practice of concluding commercial treaties had become widespread. The bilateral form of the undertakings permitted the fitting of wording to the situation obtaining between each pair of signatories, but the effect upon relations with third states was naturally a consideration, and in the course of the modern development certain "standards" of treatment were to come into wide use.

Of central importance among these standards has been that of most-favoured-nation treatment. The term is a misnomer, since it might seem to suggest preferential treatment, whereas its meaning is essentially that treatment shall be no less favourable than that accorded any third state. An obvious characteristic is the contingency involved; *i.e.*, a state obtaining a pledge of the treatment acquires nothing substantive unless some foreign state receives rights or privileges falling within the matters to which the pledge applies. The national treatment standard also involves contingency, since a state agreeing to it becomes committed to accord treatment no less favourable than its own nationals (or goods or vessels, as the case may be) receive. Modern treaties have sometimes provided, on particular subjects, national and most-favoured-nation treatment.

Still another standard is that of reciprocity (not to be confused with mutuality in the application of provisions). There have been commitments to give "equitable" treatment, or to pay "just" compensation for property taken, or (especially in connection with basic human rights) pledges to allow treaty aliens to enjoy certain freedoms without specific reference to whether other foreigners or even nationals enjoy them. There has been, as with respect to diplomatic or consular privileges and immunities (matters which have sometimes been the subject of provisions in commercial treaties), specification of international law or international usage as the measure of treatment.

An early modern example of most-favoured-nation assurance on a one-way (rather than a mutual) basis was in the Turkish capitulations, which began with respect to France in 1535. Mutually operating clauses embodying the same standard were in the treaty of 1641 (of truce, as well as commerce and navigation) between the

Netherlands and Portugal and in Oliver Cromwell's treaty of peace (1654) with Sweden. Lending itself to use either in broad terms applicable to various subject matters, or in terms that are quite specific as to what is covered, the most-favoured-nation idea has sometimes been mentioned many times in a single treaty. Application may be limited to what is accorded to named third states. Thus Spain agreed, in a treaty of peace signed with France in 1659, that French subjects should have the same liberties that Spain had granted to the English; in 1661 Denmark agreed with the English (in a treaty of alliance) that the latter should not pay more or greater customs charges than people of the United Provinces or any other foreigners paid, Swedes alone being excepted. By a treaty of commerce in 1703 Portugal agreed to remove prohibitions upon the importation of English woollens, and England to permit importation of Portuguese wines on payment of one-third less duty than was charged on French wines. The latter concession led to difficulties for the English with the Portuguese when, in connection with the peace of Utrecht (1713), it was proposed to accord most-favoured-nation treatment to products of like nature from any other country in Europe.

The United States made its first commercial treaty in 1778, with France, in connection with the treaty of alliance which the parties signed on the same day. In this treaty the most-favoured-nation pledge was on a conditional basis, in that "any particular favour . . . in respect of commerce and navigation" which either party should grant to a third state was to be granted to the other party "freely, if the concession was freely made, or on allowing the same compensation, if the concession was conditional." Evidence seems to indicate that this conditional formula was proposed by the French. In any case, the conditional form of the commercial most-favoured-nation concept continued to be a feature of United States commercial policy until 1923, when the country changed to the unconditional form. The conditional form leaves possible the withholding of a tariff concession (from a country with which there is a most-favoured-nation pledge) on the ground that the country to which the concession is made has given something in return for it. Difficulties in determining whether concessions have been gratuitous, when a state claiming them has in fact offered "the same or equivalent" concessions, and what considerations of propinquity or close political relationship might enter into findings of conditionality, may make the applicability of tariffs at a given time uncertain.

There was no common pattern of commercial policy in Europe prior to the middle of the 19th century. There was effort by France, beginning in 1786, to accomplish tariff reforms, but the wars of the French Revolutionary period interrupted this effort. Prohibitions and differential tariffs featured international commercial relations during the first half of the 19th century.

**Developments From 1860 to 1914.**—The making of the Anglo-French (Cobden-Chevalier) treaty of 1860 marked the beginning of a new era in western commercial policy. There was provision for most-favoured-nation treatment with respect to import duties; Great Britain eliminated protective tariffs, and France granted to British products rates lower than those which the French general tariff imposed. Soon France came to have most-favoured-nation relations with various other countries. One of these was Germany, with which France agreed that each of the parties would allow the other the benefit of tariff reductions granted to Great Britain. Before the end of the century, however, the French government negotiated (after 1892) a series of commercial treaties in which it agreed to accord minimum tariff rates to countries which granted satisfactory rates to France. Tariff bargaining went on in a protective atmosphere.

In the period from 1892 to 1894 Germany made what were called the Caprivi treaties, securing reductions of foreign tariffs on German goods on condition of Germany's not applying the highest rates of its general tariff. States which did not follow the lead of France and Germany in this field were Great Britain, Belgium, Denmark and the Netherlands. Having no tariffs on some products and low rates on others, they were not in position to bargain and sought most-favoured-nation treatment for their exports. The United States, despite its already-noted adherence to the principle

of conditionality, and despite some special arrangements such as those with Canada (1854-66), Hawaii (after 1875) and Cuba (after 1903), followed, in general, a policy of not discriminating against foreign goods because of their national origin.

The growing network of commercial treaties helped toward bringing about a situation in which a large part of the world's trade, in the half century before 1914, was on a basis of unconditional most-favoured-nation treatment. The principle applied for a time under the British flag to intra-empire trade, and non-British goods entered the British colonial empire on the same terms as goods from other British lands. Adoption by Canada in 1898 of an imperial preference plan led, however, to Great Britain's termination of its existing treaties with Belgium and Germany, respectively. The replacing treaties did not require the British dominions to admit non-British goods at the same (preferential) rates which might apply to British goods.

In this period was discernible also a tendency toward highly elaborate classifications in tariffs, sometimes with the object of favouring particular countries over others. A frequently cited example of this was Germany's designating (in its customs tariff, and in connection with its treaty of 1905 with Switzerland) large dappled mountain cattle or brown cattle "reared at a spot at least 300 metres above sea level, and which have at least one month's grazing each year at a spot at least 800 metres above sea level." Such classifications might facilitate denial of a favourable rate to states desiring to secure it on the basis of a most-favoured-nation pledge in terms of "like" products.

Particularly through their establishment provisions, commercial treaties provided elements of law to supplement the rules of the developing law of nations. The latter imposed upon states no obligation to admit either products or migrants from other states. Once a state had admitted aliens, there was legal responsibility for their protection. Customary international law in the 19th century did not, however, preclude a state's subjecting admitted aliens to discriminations of various kinds. Commercial treaties were able to fill the gap to a considerable extent through national-treatment and most-favoured-nation treatment clauses. Employment, in the 19th century, of certain "stock" clauses had the effect of providing in a measure, as suggested by Arthur Nussbaum in *A Concise History of the Law of Nations* (Macmillan, 1947), "a substitute for norms of . . . international law."

Treaties of this type also figured in a limited way in the development of thought concerning the peaceful settlement of international disputes. Two groups of commercial treaties signed in the 1860s contained clauses whereby the parties agreed to arbitrate disputes between them. The first group included treaties which Hawaii made with Belgium, Switzerland and Italy, respectively; the provisions on arbitration covered all disputes which might arise between the parties. The second group comprised commercial treaties which Siam concluded with Belgium, Italy, Norway, Sweden and Austria-Hungary, respectively; in each case the arbitration clause covered only disputes concerning the interpretation and application of the particular treaty.

In the last half of the 19th century and the early years of the 20th there were some commercial treaties with clauses which were of one-way application. This was notably true of some arrangements between certain western states on the one hand and, on the other, countries in which these western states obtained extraterritorial privileges for their nationals. In general, however, the principle of mutuality (the rule of two-way application) has characterized this type of treaty.

**Developments of the Interwar Period, 1920-1939.**—While world conditions from 1914 to the end of World War I were not very propitious for the making of commercial treaties, the years which followed saw renewed effort in this direction. All states were not equally vigorous in promoting nondiscrimination in tariff matters. France, for example, which had in 1918 announced its intention to terminate all of its commercial treaties, did in fact allow many of its old treaties to remain in force, but in new treaties agreed to the application of the most-favoured-nation principle only to particular groups of articles. Other European states evinced reluctance, after 1920, to extend most-favoured-

nation treatment. The United States, in 12 commercial treaties signed during the period between World Wars I and II, the first of which was with Germany in 1923, emphasized its change from the conditional to the unconditional form of most-favoured-nation commitments. In furtherance of its new policy the United States government also announced that it would not request Brazil to extend for a longer time the preferential rate which that country had for some years given to a small number of products from the United States. Under authorizing legislation of 1934, the United States began to conclude reciprocal trade agreements. These contained tariff schedules and pledges of most-favoured-nation treatment, but with exceptions for preferential rates which the United States accorded to Cuban products.

Some preferential practice also featured British commercial policy. The Ottawa agreements of 1932 dealt largely with imperial trade preferences in the form of tariff rates, but included some quota arrangements. In 1933 Great Britain concluded with Argentina the so-called Roca-Runciman agreement, which related to tariff rates and also to British quotas, as well as to the administration of Argentina's exchange control in such a way as to favour British commerce. Other British commercial arrangements of this same period, particularly with countries of northern Europe, resulted in special treatment of British trade, and were in contrast to some earlier emphasis upon nondiscriminatory treatment of foreign goods in general.

In the period between World Wars I and II the making of commercial treaties was affected by resort to new methods of trading and the introduction of new techniques in state control of trade, as well as new types of restrictions upon economic activities of resident foreigners. Whereas previously the problem had been largely that of securing equal tariff treatment of trade that was largely in private hands, there came to be questions of how to achieve nondiscriminatory treatment when governments themselves engaged in commerce on a considerable scale. The Soviet Union, in commercial treaties of the period with such countries as Germany and Italy, sought to provide for the operations abroad of its trading delegations. With the economic collapse of 1931, new forms of economic nationalism worked against traditional liberal concepts of international trade. Along with state trading, there were quota restrictions upon imports, and monetary regulations. In the 1930s quota or exchange restrictions, or a combination of these, largely replaced tariffs as effective controls in France, in eastern and southern Europe and in South America. New type provisions against discrimination came into use both in commercial treaties and in trade agreements.

There was also development and expansion of provisions on certain establishment matters. There was, in commercial treaties of the United States, for example, extensive use of the national-treatment standard. In some instances rights given to aliens to engage in listed types of work applied even to practice of the professions, and there were treaty pledges for extending benefits of workman's compensation laws to treaty aliens on a national-treatment basis. In the matter of companies' rights, commercial treaties which the United States signed provided for each party state's recognizing the juridical personality of companies organized under the laws of the other party, and made a beginning of allowing aliens to organize local companies (on a most-favoured-nation basis); but the actual functioning of foreign corporations in the territory of each party state was left within the control of that state.

**The Post-World-War-II Period.**—Of the principal commercial countries of the world, the United States was in by far the best position, after the cessation of hostilities in 1945, to advocate liberal principles in commercial policy. Obstacles to the restoration of world trade included the practices which various countries followed in discriminatory use of exchange controls, quantitative restrictions on imports, and the carrying on of commercial activities by governments themselves. The United States, which had made no use of exchange control and very limited use of import quotas, took the initiative in efforts looking to a new multilateral arrangement on trade, as well as in the conclusion of new bilateral treaties. The latter were in terms consistent with the multilateral approach to

international trade while also putting into practice some new establishment provisions designed to provide more adequate security for investors (as well as traders) and for nationals of one party state residing in the other party state.

Effort for a multilateral agreement took the form of a project for an international trade organization, the actual formulation of the scheme being undertaken through conferences held under auspices of the economic and social council of the United Nations. Fifty-four states signed the charter of the International Trade organization, an instrument designed to cover the whole field of international trade but not to fix or bind tariff rates, the latter activity being left for handling in separate negotiations. As finally elaborated at Havana, the charter contained not only provisions on commercial policy, but also chapters on such other matters as employment and economic activities, economic development and reconstruction, restrictive business practices, and intergovernmental commodity agreements. While the charter as such did not come into force, most of its provisions on commercial policy did become operative through the General Agreement on Tariffs and Trade (G.A.T.T.) which 23 states negotiated in 1947 (see **TARIFFS**). The agreement came into force provisionally in 1948; by the early 1960s 38 states were contracting parties and several others participated under special arrangements. Under the agreement, and through a series of conferences, pairs of states negotiated reductions in tariff rates. The failure of the states to bring the International Trade organization into existence left an institutional gap which occasioned further effort. In 1954 a plan was projected looking to an Organization for Trade Cooperation, the essential purpose of which would be to administer the General Agreement on Tariffs and Trade.

Less spectacular, and more easily relatable to well-known methods in international economic relations, was the program which the United States launched for the making of new bilateral commercial treaties. Since the United States appeared to be the only major state undertaking such a program on a wide geographical basis, provisions of these treaties represented U.S. policy rather than a universal trend; at the same time the treaties presented some new formulas for correlating international pledges with national policy and integrating bilateral with multilateral engagements.

From the broad provisions on nondiscriminatory treatment of exports and imports, there were exceptions clauses to cover the long-standing preferences which the United States had given to Cuban products and also preferences to Philippine products during the period of United States wardship which began in 1946. Exceptions provisions also related the new bilateral instruments to existing multilateral engagements. For example, commitments under the commercial treaties were not to preclude action (on the part of a signatory which was a party to G.A.T.T.) that was required or specifically permitted under the General Agreement. In the field of exchange control, there were provisions in the commercial treaties designed to secure nondiscriminatory treatment, but by special wording these were not to alter the parties' obligations to the International Monetary fund; nor did the bilateral engagements preclude the imposition of particular restrictions when the fund should authorize or request a party state to make such restrictions.

In the establishment parts of the new commercial treaties there were both innovations and adaptations of long-used rules. Of the former, perhaps most conspicuous were those providing for rights of companies. These went further than had provisions in earlier treaties requiring the recognition of juridical personality, for, with considerable variation, they permitted companies organized in one party state to engage in broadly listed types of activities in the other; the standard agreed to was, in general, national and most-favoured-nation treatment, but with reservation (to parties) of the right to limit the extent to which aliens might engage in transport, communication, public utilities, certain types of banking or the exploitation of natural resources. Other provisions allowed nationals and companies of one party state to organize or acquire interests in companies of the other party state. A permissive reservation allowed a party to withhold benefits under the bilateral treaties from companies of the other party which were owned or

controlled by nationals or companies of third states; most of the treaties made it clear that such withholding would not apply to the basic rights of having juridical personality recognized, or having access to courts.

Protection of property from uncompensated taking for public use had long been an object of commercial treaties. Treaties of the United States after 1945 went further than most of the country's earlier treaties had gone with respect to aliens' acquisition of property. Whereas, for example, the pattern employed in the German-American treaty of 1923 had contained broad provisions on the leasing of land for treaty-permitted purposes, the new treaties made some application of the national-treatment standard for the acquisition of land, with some regard for the principle of reciprocity. Legal and policy questions arose, particularly in the case of federally organized states. Such property as could be acquired by treaty aliens was, in any case, the subject of rather specific protection provisions; for that which was taken by a party state for public purpose, there was to be prompt payment of just compensation, and the latter was to be in an effectively realizable form.

In many of the treaties there were provisions for national and most-favoured-nation treatment in the matter of selecting enterprises for government control or for nationalization. Government agencies engaging in business activities within the other party's territory were not to claim jurisdictional immunities therein and there were other clauses designed (within limits) to protect private business enterprises from the destructive effect of government-subsidized competition.

In the realm of human rights, there were in most of the new treaties provisions on liberty of conscience and freedom of worship. With some signatories the United States agreed to certain limits upon the drafting of treaty aliens for compulsory military service. Most of the treaties contained clauses on freedom of reporting, a subject which had not been covered in earlier treaties of the United States.

Security considerations also figured in the making of the treaties, which by their terms were not to preclude measures "necessary to fulfill the obligations of a party for the maintenance or restoration of international peace and security" or necessary to protect national security interests. In each treaty there was provision whereby disputes over its interpretation or application could, unless the parties should arrange them by other pacific procedures, be referred to the International Court of Justice.

During the 1950s and early 1960s numerous efforts were made to reduce or eliminate trade barriers among the nations of various geographic areas. A most important commercial treaty, for example, was signed in 1957 (became effective Jan. 1, 1958) by six European nations to establish the European Economic Community (E.E.C.), popularly known as the Common Market. In 1960 a similar organization known as the European Free Trade Association (E.F.T.A.) was formed by a treaty signed by seven European countries that were not at that time members of the Common Market group. In the same year a treaty was signed by seven of the leading trading nations of Latin America looking toward eventual establishment of a free trade zone. Another similar association was entered into by three small Central American states, Guatemala, Honduras and El Salvador. See also ECONOMIC UNION; PAN-EUROPEAN MOVEMENT.

(C. M. K.; F. W. F.; R. R. Wn.)

**COMMISSARY**, a person to whom special authority or a special duty has been committed or delegated. An ecclesiastical

commissary, for instance, is an official who in certain circumstances exercises the jurisdiction of a bishop (if appointed by the pope he is called a commissary apostolic). In English military contexts commissariat means the supply of food, transport, etc., to an army, the official responsible being formerly known as the commissary; the U.S. equivalent is logistics (*q.v.*), the term commissary being confined to a type of canteen (*q.v.*) selling foodstuffs. In continental armies in the 17th and 18th centuries "war commissaries" had extensive powers of surveillance, on their government's behalf, over the conduct of officers and troops and over an army's expenditure. In the U.S.S.R. the designation people's commissar (Russ. *narodny komissar*) was used for the head of a government department till March 1946, when the people's commissariats were reorganized as ministries.

**COMMISSION** is the term used to describe a multiheaded governmental agency created to perform a particular function, such as special investigation or governmental regulation of business. In Great Britain the term is most commonly used to designate commissions of inquiry, which investigate particular matters; such commissions are distinguished, according to their terms of appointment, as royal, statutory or departmental. Investigating commissions have been less frequently employed in the United States, where their functions are largely performed by legislative committees. Most commissions in the United States, on the other hand, are charged with the execution or enforcement of statutes. The most important commissions are vested with regulatory powers. They control different aspects of the economy, having either regulatory authority over an industry (*e.g.*, the Interstate Commerce commission over railroads) or over particular practices throughout the economy (*e.g.*, the Federal Trade commission over unfair trade practices).

The first U.S. regulatory commissions were set up in the states to regulate railroads. The federal government followed their example with the creation of the Interstate Commerce commission in 1887 and later with other federal commissions set up to exercise government control. While the name commission is commonest among such agencies, it is by no means universal; some of the most significant regulatory powers are exercised by the Civil Aeronautics board, the federal reserve board and the National Labor Relations board.

**United States.**—The most important federal regulatory commissions (and boards) regulate land, water and air transportation, electric and gas companies, wire and wireless communications, banking, investment markets and trade and labour practices. They range in size from 5 to 11 members. They are appointed by the president (subject to senate confirmation) and serve for staggered terms of from 5 to 14 years. Commissioners are given substantial security of tenure, since they cannot be removed from office except for cause (*i.e.*, "inefficiency, neglect of duty, or malfeasance in office"). In most commissions, the law provides for bipartisanship by requiring that not more than a majority may be from the same party.

The relationship of the commissions to the president poses many problems. Because the commissions are vested with quasi-legislative and quasi-judicial as well as executive functions, it is deemed undesirable for these agencies to be placed within the executive branch. Instead, they are set up as independent bodies, not subject to the direction or unrestricted removal power of the president. But this, in turn, places difficulties in the way of effective co-ordination of over-all executive policy. In the words of the 1937 report of the President's Committee on Administrative Management, the commissions constitute a "headless fourth branch."

The need for effective co-ordination has led to important presidential controls. The commissions' budgets must be channeled through the bureau of the budget in the executive office of the president, which controls the appropriations that the commissions may request. In addition, the commissions must clear their legislative and investigative demands with the budget bureau. The president can designate the chairmen of all the regulatory commissions except the Interstate Commerce commission. The chairmen may be removed from their chairmanships at the president's

pleasure. Under 1950 reorganization plans, the presidentially controlled chairmen were, in most of the commissions, made the administrative heads, with control over personnel and the day-to-day work of the agencies.

Besides the regulatory commissions, there are other federal multiheaded agencies that regulate internal government operations (e.g., the Civil Service commission), dispense benefits (e.g., the Railroad Retirement board) and engage in operating activities (e.g., the Atomic Energy commission). There are also government corporations (e.g., the Tennessee Valley authority) that are plural-headed, though with a different legal status than ordinary commissions.

The commission form is used in such state agencies as utility commissions, workmen's compensation boards, boards of health and education and unemployment compensation commissions. In local government they appear principally in the fields of health and education. See also ADMINISTRATIVE LAW; REGULATORY AGENCIES. For the commission form of local government, see CITY GOVERNMENT.

See Robert E. Cushman, *The Independent Regulatory Commissions* (1941); U.S. Commission on Organization of the Executive Branch of the Government, *Task Force Report on Regulatory Commissions* (1949); President's Committee on Administrative Management Report (1937); Marver H. Bernstein, *Regulating Business by Independent Commission* (1955); Bernard Schwartz, *The Professor and the Commissions* (1959). (B. Sz.)

**Great Britain.**—In Great Britain the term commission may refer to a financial, executive or quasi-judicial body or to a committee of inquiry, especially a royal commission. In general it designates a body appointed for a particular purpose, or for the carrying out of administrative functions consequent upon legislation that can only be given effect through an administrative organ. A commission is appointed when it is desired that administration shall be independent of the government department concerned. Another purpose in appointing a commission is to ensure objectivity; therefore this type of body is favoured where financial claims are involved. Commissions appointed for financial work include the Charity commission, the Title Redemption commission and the War Damage commission. Others, appointed for nonfinancial purposes, include the forestry, prison and national park commissions. The name can also be given to a public corporation administering a nationalized industry, for example, the British Transport commission.

The instrument establishing the commission may also lay down the manner of its appointment. When nonpolitical, it may be appointed by the crown; when judicial, by the lord chancellor; when nondepartmental, by the prime minister; and when departmental, by a minister. Funds are likely to be on the departmental vote concerned. Members of a commission are not generally known as commissioners; this term is usually restricted to those appointed to undertake semijudicial functions. The traffic commissioners, for example, are appointed by the minister of transport to administer the vehicle licensing systems, but are not subject to his direction.

See J. A. G. Griffith and H. Street, *Principles of Administrative Law* (1952); Committee on Administrative Tribunals and Inquiries, *Report* (1957). (E. A. J. D.)

**COMMISSIONER.** In English-speaking countries, the term commissioner is often used to designate a member of a multiheaded governmental body created to perform a particular function, such as special investigations (commissions of inquiry) and personnel management (civil service commissions).

The term commissioner appeared at the end of the 15th century in reference to officials charged by royal commission or warrant with specified duties. Under the Statute of Sewers (23 Henry VIII, c. 5) commissioners were appointed to make regulations and levy assessments. In the 16th century the crown named commissioners to hear and determine controversies affecting private rights. In 1643 the administration of excise laws was vested in commissioners authorized to punish violations. The use of commissioners rather than judges to enforce excise laws was opposed strongly. In the 19th century the phrase "government by commission" was used to criticize the determination of private rights by officials act-

ing in a nonjudicial manner and without common-law safeguards for property rights. J. Toulmin Smith (*Government by Commissions Illegal and Pernicious*, 1849) referred to commissions as "the chosen instruments of schemers and of the enemies of public liberty."

In some British possessions the head of government is called high commissioner. Under the Commissioner for Oaths act, 1889 (as amended), the lord chancellor appoints commissioners to administer oaths to persons making affidavits. The high court may order a witness to be examined on oath by an officer of the court or a commissioner in lieu of attendance in court.

In United States usage the term refers mainly to officials serving on state and federal administrative boards that regulate business conduct. The first state commissioners served on commissions established in Rhode Island in 1836 and in New Hampshire in 1844 to regulate railroads. The first federal regulatory commissioners served on the Interstate Commerce commission beginning in 1887. In states, regulatory duties are sometimes vested also in single commissioners, such as a commissioner of banking and insurance. In the federal departments of the treasury, justice, the interior, commerce, labour and health, education and welfare, some major component agencies are headed by commissioners. The title is also conferred upon certain judicial officers, such as the inferior federal officers known as United States commissioners and members of temporary state supreme court commissions. Executive officials comprising the governing bodies of some U.S. counties and commission-type municipalities are also called commissioners. See also COMMISSION; REGULATORY AGENCIES. (M. H. B.)

**COMMODIANUS**, an important Christian Latin poet, probably of African origin (Palestine and Gaul are also suggested), is likely to have flourished in the middle of the 3rd century (the 4th and 5th century also find support). He was apparently a convert to Christianity: the last poem of his *Instructiones* gives the acrostic signature (in reverse order) *Commodianus mendicus Christi*, and this description together with the epithet *Gazaenus* occurring in the poem's title may point to tenure of a curatorship of a fund of offerings (though the word *Gazaenus* has been used to suggest that Commodian came from Gaza in Palestine). No evidence supports the fragmentary testimony of the Middlehill manuscript of the *Carmen apologeticum* that he was a bishop. In the *Carmen apologeticum* he expounds Christian doctrine, dealing with the Creation, God's revelation of himself to man, Antichrist and the end of the world; in his other work, *Instructiones*, comprising 80 poems in two books, all (except two abecedarian poems, acrostic in form, he attacks pagan deities, criticizes Jews and admonishes Christians. The absence of poetic quality from Commodian's verse may be due either to didactic zeal or to realization of the unlettered nature of his audience. His idiom is that of vulgar Latin: his metre, though based on the quantitative hexameter, frequently neglects quantity and no underlying principle has been established for his verse; the view that it is based on word accent is untenable, and though there is some monosyllabic rhyme his verse less resembles rhythmical verse than the metrical inscriptions preserved from Africa (this resemblance is the strongest evidence for Commodian's African origin). Whether these important peculiarities of language and versification result from Commodian's ignorance or are intentional and attributable to his desire to facilitate communication with his audience (a view supported by his recognition of the mnemonic value of the acrostic form) cannot be determined.

See edition by J. Martin, *Corpus Christianorum, series Latina*, vol. 128 (1960). See also M. Simonetti, "Sulla cronologia di Commodiano," *Aevum*, vol. xxvii, pp. 227-239 (1953). (D. R. B.)

**COMMODITY MARKET.** A commodity market deals with the transfer of goods from producers to processors, manufacturers or ultimate consumers. Its main function is the determination of prices and the exchange of title. The term commodity usually refers to a special class of goods encompassed in the term "foodstuffs and raw materials." Wheat, corn or maize, rice, tea, coffee, sugar, rubber, tobacco, tin, lead, zinc and copper are examples of commodities.

A commodity market may be defined in a physical sense and in a functional sense. Physically, it is a specific area where buyers and sellers meet to transact business. This may be a building, a group of offices, a small town or even an assembly of huts where buyers and sellers meet. From the functional point of view a market represents the operation of economic forces, usually referred to as demand and supply, which result in the determination of prices. In this sense the market is the community of buyers and sellers and, with the aid of the telephone and telegraph, may encompass the whole world. Commodity markets are of two main types: spot or physical markets where actual goods are traded, and futures markets where trading is in contracts for future delivery.

**The Evolution of Commodity Markets.**—Wherever the division of labour and the specialization of processes take place the need for exchange arises. Because of the high cost of transportation the ancient markets were mainly local. Most of the staple commodities required for everyday use were produced in the immediate vicinity; only precious metals and high-priced luxury goods such as jewelry, silks and spices could afford the high charges involved in trade over long distances. By the time that the Greek and Roman empires flourished, commerce had advanced to the point where foodstuffs and other raw materials were traded in volume on an interregional basis. (See *COMMERCE, HISTORY OF.*)

The medieval market place was a direct descendant of the Greek agora and the Roman forum. Interregional trade throughout western Europe was carried on through the medium of fairs. The Champagne fairs, in what is now France, and similar fairs in other regions had their heyday in the 13th and 14th centuries. Merchants from all over Europe met to exchange the raw materials or finished goods of western Europe, the Mediterranean and the east. Lesser regional fairs supplemented the international fairs. Regional and local fairs traded in local produce to a greater extent.

Expansion of European trade warranted the establishment of more permanent markets by the 15th century. Merchants and trading companies gradually set up branch houses. Trading centres called bourses or exchanges were at first general market places dealing in all types of commodities. Later, some of these markets and branch houses specialized in particular commodities.

Improvements in transportation and communications resulted in an expansion of the network of world trade in early modern times. Luxuries were replaced by the cheaper staples. Commodities such as sugar, tea, coffee and cocoa were imported in greater volume from tropical areas and the grain markets widened to encompass all of Europe and later the whole world.

Throughout the 19th century and well into the 20th century the network of world trade in commodities developed largely through the initiative of private enterprise working within the framework of free-trade principles. The incidence of two world wars and the depression of the 1930s, however, created conditions in which free markets could not function properly; surpluses and wide fluctuations in prices occurred. As a result of these factors, plus the growth of state intervention in the economic sphere, few commodity markets in the world remained free from government regulation.

**Physical Markets and Marketing Agencies.**—The movement of agricultural commodities is generally from a large number of producers to many small primary markets. Supply is further concentrated by shipment to central markets where the commodity is sold to processing organizations or to wholesalers, supermarkets and retailers. In the case of ores and metals the initial process of assembly is not as widespread because the ore is usually shipped directly from the mine to the smelter or the fabricating plant.

Commodity markets are linked through the buying and selling activities of the various marketing agencies. Offers to sell and bids to buy are sent by telephone or telegraph from the local to the central markets and vice versa. Prices tend toward equality in each market, subject to differences in transportation costs. Spot or present prices differ from futures prices because of the costs of storage, insurance and financing and because of shifts in the outlook for supply and demand.

The centre of commodity trade consists of the mercantile houses,

brokers and agents located at the central markets. The nucleus is usually the building that houses the exchange or trade association. These associations promote orderly trading by formulating rules, establishing standard contracts and arbitrating disputes.

Many different grades or qualities of a commodity are available for sale at terminal markets. The buyer is usually able to acquire the exact type and grade of the commodity he wishes from the huge volume stored there or at nearby points. The majority of the purchasers at such markets are the large consumers, such as spinners for cotton and wool, packing houses for livestock and millers for wheat. In export markets, brokers or other agents of foreign importers are also important buyers.

In former days trading on the physical market took place in actual sight of the goods because of the primitive nature of the marketing services and the lack of recognized standards of quality and systems of grading. Goods are now sold on description by grade, with arbitration facilities available in case of dispute. Contracts on various markets are standardized and each trader knows the terms on which he is dealing. The goods need not be on hand at the market but may be in transit or stored in a warehouse. There is also little need for buyers and sellers to meet in person. Quotations are known to prospective buyers who may submit bids by telegraph, telephone or mail without actually seeing the goods. Payment is by check and title passes with the transfer of a warehouse receipt or bill of lading. The concept of a market as a place where the actual transfer of commodities takes place, therefore, is nonexistent in the case of many commodities, particularly after the assembly stage at country markets is passed.

In the country markets the local dealer is usually the principal buying agent and the producer is the seller. The dealer buys, usually for cash, at the local market or he may visit each farm individually and conduct his purchasing operations there. Among the other marketing agencies that operate on the numerous local markets are co-operatives, representatives of processors, large merchant traders, storekeepers and moneylenders.

On central markets a variety of market agents are also at work. A producer who wishes to bypass local markets may consign his goods to a commission agent on the central market. Local dealers sell to processors or large merchant firms on the central market. Large co-operatives have their sales offices there and large producers sell through an agent. Foreign importers and processing houses also have representatives in large export markets who will purchase from local merchant firms or they may even extend their organizational lines back to the producer. Jobbing firms on central markets purchase in large quantities and then break them up into smaller quantities for sale to small purchasers.

Where the marketing agent purchases the commodity outright and takes title to it his remuneration is in the form of profit or markup on the selling price of the goods over his purchase price. The country dealer, wholesale merchants, processors and retailers all are remunerated in this manner. Other marketing agencies may have possession of goods but they do not have legal title. A broker and a commission house are examples of independent agents who perform marketing services for their principals, who retain title to the goods. Their remuneration is obtained in the form of a fee or commission.

**Commodity Exchanges.**—The function of a commodity exchange or futures market is different from that of a commodity market. The latter is concerned with trading in a specific quantity and grade of a commodity for present or forward delivery; the former is concerned with the purchase and sale of an enforceable contract to deliver a commodity at some future date. The seller of a contract on a commodity exchange does not normally intend to deliver the actual commodity nor does the buyer intend to accept delivery; each will, at some time prior to the date of delivery specified in the contract, cancel out his obligation by an offsetting purchase or sale.

The reason for this behaviour is clear enough. The parties do not wish to enter into the physical operations of marketing but to engage in one of its aspects, namely the assumption or delegation of the risk involved in a change in price. A businessman normally earns his income through the performance of some service such

as assembling a commodity, storage, delivery to a consuming area, fabrication, etc. He usually has insufficient capital to assume the risk of loss through a change in price while he has title to the goods. To avoid this risk he has recourse to the futures exchange, where he can pass on the risk of price change to someone else. The method by which this may be done is easily understood. A middleman who buys a commodity may sell at the same time a futures contract for an equivalent amount, *i.e.*, he assumes an obligation to deliver at a future date. Sometime later he sells his holdings of the commodity; simultaneously he purchases a futures contract and thus cancels out his obligation on the futures exchange. In the interim between the purchase and sale of the actual commodity its price may have fallen. Normally the price of the futures contract will also fall. He would lose money on the physical transaction but would make a profit on the futures transaction because he would be able to buy back his futures obligation to deliver at a lower price than he sold it. Had the price of the commodity risen, he would have profited on the physical transaction and lost on the futures transaction.

A similar transaction may occur when a processor contracts to sell a certain quantity of a manufactured product at a specified price for future delivery. When the time of manufacture arrives he must buy specified amounts of raw materials. To protect himself against a rise in the price of the raw materials in the interim, as compared with the price prevailing when he contracted to deliver the manufactured goods, he purchases a futures contract which he will close out with a sale when he buys the physical raw materials sometime later.

Such transactions on the futures exchange are made possible through the presence of speculators. Their operations on both sides of the market result in a greater volume of transactions than the actual volume of physical transactions. This makes for a more continuous market. The speculators are constantly on the alert for abnormal spreads between different futures exchanges as, for instance, at New York city and London, or between different delivery months on the same exchange.

Futures exchanges are thus ancillary to commodity markets. They do not compete with or supersede the spot or physical markets but rather complement them by performing functions which the latter cannot. They provide insurance against the risk of price changes and also provide a basis for the determination of prices at which commodities are actually traded.

Exchanges are incorporated as nonprofit organizations. Membership is by election and the purchase of a "seat." Members are privileged to trade on the exchange for their own account or for the account of their clients subject to the rules of the exchange. Trading is in terms of a unit of a standard contract. For instance, on the New York Coffee and Sugar exchange there are two coffee contracts: a B contract for 32,500 lb. of Brazilian coffee and an M contract for 37,500 lb. of mild coffees, each of a designated basic grade.

The settlement of contracts made between members of an exchange is effected through clearing associations affiliated with each commodity exchange. At the end of each trading day, every member's net market position is determined. Thereafter the clearing house assumes the responsibility for all accepted contracts and guarantees performance.

Futures contracts relate to a specific month, several of which are traded in at any one time. When the actual month of delivery arrives all outstanding contracts must be settled by delivery of the commodity. Any seller of a contract who has not closed out his position by choosing to make delivery may do so on any trading day he selects during the month in question. A transferable notice to this effect is forwarded by the seller to the clearing house for each contract outstanding. These notices are delivered by the clearing house to members who are net purchasers for that particular month. Each such purchaser, should he not elect to accept delivery, may sell a contract for that month and thus cancel out his net position and pass the notice on to the buyer of the contract after endorsement. This may occur throughout one business day until some purchaser decides to take delivery and "stop" the notice.

## TYPES OF MARKETS

**Grain Markets.**—Before the depression of the 1930s most grain was handled on a free international market. In the Canadian system the farmer usually delivered his grain to the country elevator and sold it for cash or shipped it to a terminal market such as Winnipeg, Man., or Vancouver, B.C., for sale there by a commission house. The grain purchased by private companies was usually hedged on the Winnipeg futures market and sold to exporters at the ports. Large co-operatives played an important marketing role. In the United States grain was handled in a similar manner. Kansas City, Kan., and Minneapolis, Minn., were leading spot markets but most transactions, particularly on the futures market, took place in Chicago, the world's largest grain market. Shipment for export took place through Duluth, Minn., the Atlantic ports (particularly in winter) and the Gulf of Mexico ports.

Both Canadian and U.S. grain was sold on government grade and certification, usually in bulk. In Australia and Argentina the prewar trade was in bags and sale was by a standard of "fair average quality." Australian wheat was sold on description by the state in which grown or, if without description, as "all ports." In Argentina standards were established for three districts: "Rosafe" for wheat grown near to and shipped from the ports of Rosario and Santa Fe, "Baril" for the types grown near Buenos Aires and "Barusso" for wheat grown around Bahia Blanca.

The leading import market was the United Kingdom, with London and Liverpool as its centres. The grain for these markets was usually purchased on a free on board (f.o.b.) port-of-shipment basis and sold at a price that included cost, insurance and freight (c.i.f.). The trade was handled under traditional and standardized forms of contract developed by the Corn Trade association. In addition, there were facilities for trading in futures which, in London, were located in the Baltic Mercantile and Shipping exchange and controlled by the London Grain Futures Association, Ltd.

In the 1930s marketing boards and other agencies were established to handle the mounting surplus problem. During World War II and in the immediate postwar period international allocation of exports was adopted. This was followed by the revival of the International Wheat agreement as a means of guaranteeing markets for exporting countries and supplies for importing countries within a certain price range.

The marketing of wheat and some coarse grains in exporting countries came to be largely controlled by governments. In the United States the prices were maintained at a relatively high level through the granting by the Commodity Credit corporation of "non-recourse" loans, with stored grain as collateral, and by direct purchases. The level of price support was established annually under the authority of the Agricultural Adjustment act according to a formula based on the prices of goods farmers buy. Participating producers in the marketing agreement were assigned acreage quotas or allotments. The acreage reserve program of the soil bank also provided compensation for farmers who reduced their acreage below the allotment level. By these means acreage was curtailed, excess production was held off the market and domestic prices were maintained above international levels. Sales abroad, therefore, could be made only if subsidies were granted. Surplus grains were also exported under various aid programs which provided supplies to importers with payment in local currencies or, in some cases, free of charge.

In Canada the internal marketing of most grains was placed under the control of the Canadian Wheat board but the selling function at the terminal market was in private hands except for intergovernmental contracts. Also, internal handling, storage and shipment functions were carried out by the trade acting as agents of the board. Wheat, barley and oats were placed in annual pools in which producers shared the profits. No rigid production controls were maintained but a delivery quota system was based on each producer's certified acreage. There was no futures market for wheat but the board established daily selling prices, in line with competitive world prices, and permitted a deferred pricing policy on export sales whereby the purchaser had the opinion over a cer-

tain period of time to close the sale at the price on the day of purchase or on any subsequent day.

In Australia all wheat was marketed through the Australian Wheat board on a pool basis. Most barley was sold through state marketing boards, also on a pool basis. The marketing of oats and maize was largely in the hands of private traders.

In Argentina prior to 1946 local grain marketing functions were performed by merchant brokers and the large export houses. During the ten-year period of control by the I.A.P.I. (Instituto Argentino para Promoción del Intercambio) it was handled by producer cooperatives and all grain marketing was controlled by the I.A.P.I. Grain exchanges and future markets were closed down. The National Grain board assumed control over internal grain marketing. This board, the sole purchaser of wheat at fixed prices, sold to the trade for export. The board also stood ready to purchase coarse grains at guaranteed prices and such grains purchased by the trade could be exported only with the approval of the board. All export sales were under the "aforo" system which determined how much of the foreign exchange that an exporter received had to be exchanged for pesos at the relatively low official rate of exchange and how much could be exchanged at the relatively high free market rate of exchange. By varying the "aforo" the export price could be controlled. The board also sold wheat directly to foreign governments under bilateral agreements.

Rice production and consumption is largely restricted to the far east where 95% of the world's rice is produced. Most rice is consumed in or near the area of production so that the volume entering into international trade is small. The main far eastern exporting countries are Burma, Thailand, Vietnam and Cambodia. They supply low-quality grades for export to nearby countries. High-quality rice for the European market is supplied largely by non-Asiatic exporters such as the United States and Italy.

Unhusked rice or paddy is purchased in the villages at harvest time by millers' representatives, dealers, local moneylenders and merchants. It is usually shipped to the mills in small boats which ply the canals and streams in the deltas of the main producing areas. Most mills supplying the export trade are located at ports such as Rangoon, Bangkok and Cholon. Sale for export is usually made on the basis of examination by the buyer or his agent. There is no rice futures market or well-organized spot market.

After World War II there was a considerable degree of government market intervention. In Burma the State Agricultural Marketing board was given control of exports, a large proportion of which were sold on an intergovernmental contract basis. Paddy was purchased by the board from the producers at fixed prices and milled under contract. The board also purchased rice from the mills. The rice was sold at a price that yielded profit to the state. In Thailand a sizable export tax channeled a large sum of money into the state treasury. In importing countries also there was a considerable degree of control over both import and domestic markets.

**Fibres Markets.**—Many types of fibres enter into marketing channels but cotton and wool are the most important. The United States is the largest supplier of medium-staple cottons, which represent the bulk of the trade; it is followed by Mexico, Brazil and Pakistan. Egypt is the chief supplier of long-staple cotton. The main international markets are western Europe and Japan.

The chief U.S. physical markets for cotton are at Memphis, New Orleans, Dallas and Houston. Most Mexican cotton is concentrated and shipped through Brownsville, Tex. Important markets for other cottons are in Alexandria, Bombay, Karachi and São Paulo. Large markets in cotton-importing countries are in Liverpool, Le Havre, Bremen, Milan and Osaka. The most important futures markets are at New York, Chicago, New Orleans and Liverpool.

In the United States there are three principal types of cotton markets: local, central and mill markets. The cotton merchants operating on the central markets perform an important function in being able to supply a wide variety of cotton qualities to buyers on short notice. The mill markets are found mainly in New England and the southeastern states. Here are located the offices of the mill buyers and of the various sellers of cotton.

The United States market witnessed the entry of the government as the foremost buyer and seller of cotton through a price support program similar to that outlined above for grains. Domestic prices were maintained at levels higher than the international price. The export trade, therefore, was dependent upon government subsidies.

Liverpool spot and futures trade is concentrated at the Liverpool Cotton exchange. The city is also a mill market because spinners usually place their orders there. The cotton dealers include agents of foreign exporters operating on a commission basis, merchants or importers on their own account and mill buying brokers.

Wool production may be classified as carpet wool and apparel wool. The former is produced largely in Asia, New Zealand and South America; the world's exportable supply of apparel wool comes mainly from five countries: Australia, New Zealand, South Africa, Argentina and Uruguay. Apparel wool is classified into grades according to its fineness. The best and finest wools come from Merino sheep, medium types from crossbreeds of Merino and English breeds and coarse wools from non-Merino breeds. The chief import markets are Europe, the United States and Japan.

In Australia, as in New Zealand and South Africa, wool is sold at a series of auctions. The wool is clipped, classed and pressed into wool packs in the shearing shed. The bales are then shipped to brokers in the auction centres. The broker catalogues the wool he has to offer and displays representative bales on the show floor for examination by prospective buyers. Similar auctions are held in London, the main distributing centre for wool in Europe. In Argentina and Uruguay the wool is forwarded to brokers or commission agents in seaport towns and sold to foreign exporting firms or dealers.

Boston is the recognized central market for the apparel wool trade in the United States. Business is conducted in imported and domestic wools. The latter are usually sold shortly after shearing time to traveling buyers of Boston firms and manufacturers' agents, although some wool is sold under contract before shearing. Wool is also consigned by producers to Boston commission agents or growers' co-operatives.

There was little government intervention in world wool trade—apart from World War II—and the system of pricing permitted wool to be freely traded on international markets. Sharp changes in the demand for wool resulted in severe fluctuations in prices. U.S. wool producers were granted special aid in the form of a subsidy, which represented about 40% of the wool growers' returns but production continued to decline slowly.

**Beverages.**—The three most important beverage commodities are coffee, tea and cocoa. Coffee is produced largely in Brazil, Colombia, Central America (including Mexico), numerous countries in Africa and in Indonesia. The chief import markets are the United States and western Europe. Three types of coffee are principally produced: the high quality mild arabian types of Colombia, Central America and parts of Africa; Brazils, a generally soft arabica coffee of medium to low quality; and robusta, a low-quality coffee produced largely in Africa. Important export markets are Santos and Rio de Janeiro in Brazil and Medellín and Manizales in Colombia; other markets of lesser importance exist in all exporting countries. The chief import centres are New York, Le Havre and Hamburg, although many other markets exist. Futures markets operate in New York, Santos, Rio de Janeiro, Le Havre and London. The two latter deal only in robusta coffee.

Uniform contracts for transactions in green coffee have been adopted by various trade associations such as the Green Coffee association of New York. In the United States a large proportion of the coffee is purchased on an f.o.b. basis although African coffees are usually traded on a c.i.f. basis.

Large U.S. roaster firms purchase and import about 60% of the coffee; the remainder represents imports by nonroaster importers and exporters' agents. In Europe the importer plays a much more important role because the roasters do not operate on such a large scale as in the United States. The U.S. importer-jobber buys coffee in foreign ports, usually through a branch office located there or through an agent, and sells it to roasters or other importers.

The exporters' agent sells coffee owned by a shipper in the exporting country to importer-jobbers and roasters. Trade is usually transacted on the basis of samples which are roasted, brewed and tasted by the purchasers prior to sale.

The world coffee market is subject to long production and price cycles which have been aggravated by government intervention measures. In the 1920s Brazil adopted permanent measures to "defend" its coffee market. Prices were maintained at artificially high levels by holding coffee off the market. This generated a coffee boom which produced vast surpluses and low prices during the 1930s. During World War II capacity was reduced and in the postwar years production was insufficient to meet the demand. The consequent price rise caused another boom in planting which again resulted in surpluses. Brazil, Colombia and 13 other Latin-American producers then attempted to restrict exports through a stockpiling program in order to slow down or halt the decline in prices.

World tea production includes green, oolong, brick and black teas. The latter is by far the most important in international trade. Black tea is produced mainly in India, Ceylon, Indonesia, Pakistan and Kenya; the United Kingdom is by far the largest consumer. Black tea production is largely a plantation industry. The tea companies are grouped into associations and usually have their head offices in Europe. They are well organized for concerted action in the furtherance of their interests. At the other end of the marketing chain, particularly in the United Kingdom, the market is dominated by a relatively few firms that blend, package and distribute tea.

Black tea sale is by auction. The three most important markets are London, Calcutta and Colombo. The London auctions held at Plantation House, Mincing Lane, are the most important. Tea is put up for auction by selling brokers who sample, catalogue and exhibit it. Purchasers at auctions are usually buying brokers who act for their clients. They estimate the value of the tea on the basis of the brew made from the samples. Buying brokers also purchase on their own account and resell to dealers and blenders.

Tea prices have fluctuated less than the prices of other commodities because of the control exercised over supply. In 1933 a voluntary International Tea agreement was formed by the tea associations of India, Ceylon and the Netherlands Indies (now Indonesia) in order to control the volume of tea placed on international markets. Export quotas were determined and administered by the International Tea committee in London. The agreement was extended for five-year periods into the postwar years but was then allowed to lapse.

World cocoa production is concentrated in west Africa and Brazil. Less important producing areas are in Ecuador and in the Caribbean. The import markets are largely located in Europe and North America. The most important cocoa markets are New York and London.

Before World War II cocoa marketing was in private hands. The market was dominated by large buyers and large processors. After the war government marketing boards in Ghana and Nigeria and the Cocoa Marketing department of the Bank of Brazil dominated the supply. A considerable proportion of sales was made directly to the manufacturers through private treaty. The manufacturers also utilized the services of brokers, some of whom bought on their own account for resale to small manufacturers. After the advent of the cocoa marketing boards in Ghana and Nigeria the assembly of cocoa in the producing areas of these countries was regulated. Buying prices were usually fixed for each season and the producer sold to licensed buying agents.

**Sugar.**—Sugar is produced in tropical countries from the sugar cane plant and in temperate zone countries from the sugar beet. As most importing countries produce either sugar beet or sugar cane, the industry is generally protected in the interests of domestic producers. In addition a number of protected areas known as "preference" markets exist. The two most important are the United States and the Commonwealth of Nations. Such preference markets account for about 60% of the sugar entering into world trade. Producers within these markets are normally allocated a quota of the consumption in the respective metropolitan markets

where sugar prices are kept high. The remaining world supply moves at low prices on the "free" market, a term referring to those exporting and importing countries not directly affiliated with any political system.

The free market was in a more or less chronic state of overproduction during the first half of the 20th century, except for a few years following World War I and again after World War II. One reason for this was that in times of scarcity countries turned to the free market for their residual supplies. Thus, following the two world wars, western Europe imported heavily from tropical sugar cane producers while its own sugar beet industries were being rehabilitated. Similarly, preference markets have relied upon the free market for their marginal supplies and for additional supplies during periods of temporary shortages.

In consequence of these market forces—and also technological improvements in production—the free market suppliers have expanded their capacity beyond the "normal" requirements of the free market importers. During the 1930s and the 1950s overproduction, surpluses and relatively low prices were characteristic of this market. The result was the formation of an International Sugar agreement in 1937, and its revival after the Korean war. Under the agreement exporting countries were assigned annual export quotas in line with prospective demand in order to maintain the price of sugar at a remunerative level.

**Metals.**—Trade in metals and minerals differs somewhat from that in agricultural commodities for several reasons. Mineral resources are more highly concentrated than agricultural resources and may be exploited by larger operating units; capital requirements for metal production may be exceedingly high and call for an integrated operation through to the fabrication stage. Thus in the aluminum industry there are three large companies in the United States and one in Canada. The latter supplies the United Kingdom with most of its requirements plus the residual requirements of the United States. In view of this high degree of integration most trade in aluminum is carried on directly between fabricators and the large aluminum manufacturers. The steel industry is similarly integrated. About 85% of the iron ore produced in the United States is shipped directly to affiliated companies. Most iron ore trade is based on long-term contracts; spot purchases are relatively unimportant. In copper the degree of integration is less than in aluminum and steel, but the supply is largely in the hands of a few companies. In the United States four companies operate about 90% of the smelting capacity and two of them control the Chilean output. Two firms in Canada and a few in Africa control most of the world's remaining output outside the U.S.S.R.

The largest metals markets are in London and New York. The London Metal exchange and the metals section of the Commodity exchange in New York are futures markets dealing in copper, tin, lead and zinc. The London exchange price is widely used for spot trading in copper and tin. In the United States, however, two sets of copper prices are used. Quotations of the large integrated copper producers are used largely for these companies' own operations. Those of the custom smelter more closely reflect market conditions. Another world copper quotation of importance is that of the Union Minière du Haut Katanga in the Congo. It is fixed independently but varies in line with the London metal market and the U.S. customs smelters' prices.

The Singapore and Penang tin smelters match daily production with bids received during the previous evening and early morning. The highest bid which will close out the available supply for the day becomes the price at which the tin is sold to all successful bidders. The tin market differs from other metal markets in that an international agreement among the main suppliers outside the U.S.S.R. is in force. An attempt is made to control daily spot prices at London within a range through purchases and sales from a buffer stock. This is supplemented by export quotas.

#### PRICE FLUCTUATIONS AND SURPLUSES

In deciding on an appropriate level of output, producers are guided by the prices of commodities relative to their costs of production. Favourable prices and expanding markets will nor-

mally call forth increases in production; unfavourable prices and contracting markets will cause decreases in production. Generally speaking, however, the capacity to produce basic commodities is not easily expanded in a short period of time.

Commodity markets were plagued during the first half of the 20th century by World War I and economic devastation in a large part of Europe, by the depression of the 1930s and by World War II. These phenomena caused large general fluctuations in commodity prices. During the phase of rising prices the prices of commodities exported by raw-material-producing countries rose relative to the prices of the manufactured goods they imported. Thus their "terms of trade" improved. Conversely, during the falling price phase their terms of trade declined. Long-term basic economic factors such as changes in demand or taste, the development of substitutes, improvements in technology, new discoveries of resources and cheaper transportation facilities have affected individual commodity markets and specific producing areas in addition to the general movements caused by war and the business cycle.

Primary producers have been reasonably successful in expanding capacity to meet a growing demand but usually have been unable to reduce capacity in response to a decline in demand. Hence during periods of low prices and surpluses producers often combine to force political action in their favour. Such tactics are usually successful in cases where the producers as a group are politically powerful but represent a small segment of the economy of a nation so that they can be subsidized without unduly burdening the rest of the economy. An example of this situation is seen in the United States. Producers of certain commodities, such as cotton, corn and wheat, have been successful in maintaining relatively high prices for their products through subsidies and intervention in commodity market operations in spite of surpluses.

Another example of interference in commodity markets occurs when exporting countries are dependent for a large proportion of their foreign exchange earnings on one or a few commodities. Falling prices and surpluses have, in such circumstances, often forced intervention. Where one country has control over a large proportion of the world supply of a commodity such action may be unilateral. Where, however, a number of countries control the supply, international agreements or cartels are resorted to. Both of these situations have occurred on the world coffee market.

It is usually advantageous for smaller producing countries to avoid such agreements because they stand to benefit from any price support measures adopted without being hampered in expanding their exports. Such advantage is lost, however, if too many countries abstain. An example occurred in the world cotton market where the United States attempted to maintain relatively high cotton prices. Other countries took advantage of this situation by expanding their exports at slightly lower prices. Such tactics resulted in a progressive decline in United States' cotton exports. Thereafter the United States adopted a policy of subsidizing exports, which lowered world prices for all.

Countries that import raw materials and food stand to benefit directly from surpluses and low prices in world commodity markets, although they may lose indirectly in the form of shrinking markets for their own manufactured goods. Generally speaking, importing countries have been reluctant to enter into international commodity agreements unless some special interest is involved. Thus they joined the first International Wheat agreement in 1949 because at that time wheat was in short supply and the agreement guaranteed certain minimum quantities at a price below the prevailing price outside the agreement. On the other hand, the United Kingdom refused to participate in the second agreement presumably because it felt that it was being used by exporting countries to maintain artificially high wheat prices. The United States has traditionally been opposed to international cartel agreements and, for instance, refused to participate in the Stevenson plan for the restriction of rubber exports in the 1920s.

**COMMODUS** (LUCIUS AELIUS AURELIUS) (A.D. 161–192), Roman emperor 180–192, was born at Lanuvium on Aug. 31, 161, son of the emperor Marcus Aurelius. His reign ended 80 years of internal concord in the empire. It is true that he inherited a protracted and costly war, and the aftermath of a devastating plague. The war had started (167) as a punitive expedition against troublesome peoples across the middle Danube. The Roman attack was totally defeated; the enemy overran the greater part of the region now known as the Balkans and invaded northern Italy for the first time in four centuries. By 172, however, the line of the Danube had been recovered, and the Roman armies crossed the river with the intention of incorporating the border peoples into the empire. After three years of heavy fighting the campaign was sharply interrupted. Believing a rumour that Marcus Aurelius had died on the Danube, the commander in chief of the armies and provinces of the eastern Mediterranean, Avidius Cassius (*q.v.*), marched on Italy to seize the person of the young Commodus. The rumour was soon disproved, and Cassius was killed by one of his officers. The motives of the parties are obscure. Cassius moved against the commander of the Danubian armies, Claudius Pompeianus, who favoured victory at any price. The nobility of the wealthy provinces of the east were still in a decisive minority in the senate and the imperial council, but contributed the larger share of imperial taxation, while their interest in the annexation of the territory north of the Danube was remote. How far these and other causes were active factors in the dispute is uncertain, but one contemporary north African inscription refers to the rebellion of Cassius and its aftermath as "the rising of the east" (*motus orientalis*). Marcus judged it prudent to leave the Danubian front for an 18 months' tour of the east, allaying the tensions behind the trouble. Returning in 176, he took Commodus to the front and proclaimed him joint emperor with himself. Two opposing principles had hitherto governed the succession; the senatorial aristocracy wished the emperor, in consultation with the elder statesmen, to choose "the best man" among themselves as his successor. The army, and the bulk of the provincials, apprehensive of the risk of civil war that attended a doubtful succession, preferred a hereditary succession. The conflict of ideas had been masked for three generations since none of the four previous emperors had been survived by a son. Marcus' decision, clearly inspired by the threat of civil war provoked by the rumour of his death, made Commodus the embodiment of the concept of hereditary succession, as opposed to the principle of choice by emperor and senate of "the best man" among the elder statesmen. For portrait see article ROMAN HISTORY.

Commodus, aged 18, was still on the Danube when his father died on March 17, 180. His accession speech, presumably drafted by Pompeianus, proclaimed the aim of "extending the Roman empire as far as the ocean [the Baltic]" but he soon abandoned this formidable project. The restored Danubian frontier was not again seriously breached for almost 80 years, and Commodus' other wars were few. The most serious was in Britain where one of the walls was breached c. 180. Though the enemy was expelled, the army was demoralized and intermittently mutinous for 15 years.

After the war, the emperor and the Latin aristocracy of the senate became opposed. Commodus made Aelius Soterus, a Bithynian, his principal minister. The son of Claudius Pompeianus attempted to murder Commodus, and Soterus was assassinated, to be replaced by an Italian knight, Tigridus Perennis. He was removed in 185–186, when the senatorial officers of the insubordinate army of Britain sent 1,500 lancers to Rome to demand his execution, on a charge of plotting for the throne. Commodus agreed, and replaced him with the Phrygian Cleander.

The return of political violence, absent since the murder of Domitian in 96, was not confined to the aristocracy. After the long war, the west was full of deserters and runaway slaves. Maternus, an ex-soldier, raised a peasant force and seized many towns in Gaul and Spain. He was put down in a full-scale "War

of the Deserters" by the future emperor Pescennius Niger, but his guerrillas tried to seize Rome. The plan was betrayed only just in time, the prelude to a long series of peasant rebellions.

Commodus' part in these dramatic events was slight. Toward the end of his reign his eccentricities turned to insanity. Dressing as Hercules, he renamed Rome "the colony of Commodus" and spent much of his time with gladiators and in the arena. With the death of Cleander (c. 190) political influence passed to the emperor's mistress Marcia, the prefect Laetus and the chamberlain Eclectus. The veteran Pertinax became city prefect, while his friend and associate Septimius Severus, with his brother Geta, were given command of five legions on the Danube. The army of Britain went to Decimus Albinus, that of Syria to Niger. Commodus proposed to assume the consulship on Jan. 1, 193, armed as a gladiator and in procession from the gladiators' barracks. The offense to public decency was enormous. Marcia and her associates had him strangled during the night of Dec. 31, 192, and a grateful senate proclaimed Pertinax emperor before the imperial guards woke at dawn.

(JN. R. M.)

**COMMON LAW**, the body of customary law, based upon judicial decisions and embodied in reports of decided cases, which has been administered by the common-law courts of England since the middle ages. From this has evolved the type of legal system now found also in the United States and in most of the member states of the Commonwealth of Nations. Common law stands in bold contrast to the rules developed by the separate courts of equity (*q.v.*), to statute law, *i.e.*, the acts of legislative bodies such as parliament, and to the legal system derived from civil or Roman law now widespread in western Europe and elsewhere. In certain contexts common law can mean law which is applicable to a whole country and therefore not merely local or particular in its authority. The history of the English common law reveals the origin of these various meanings of the term.

**Development of English Common Law During the Middle Ages.**—In early medieval England law was a local and particular phenomenon. There was no national law applicable to the whole country, although some of the elements of such a law were present in the broad basis of Germanic custom which had persisted from the period of the Anglo-Saxon settlement. However, the various tribes of invaders retained a number of individual characteristics. It was only with the achievement of political unity toward the end of the Anglo-Saxon age that there came into existence a body of law applying to the whole land, with one king to enforce it. Even at the beginning of the 12th century, the *Leges Henrici primi* ("Laws of Henry I," written c. 1113-18) could refer to a threefold division of English law, following the old political boundaries: the law of Wessex, the law of Mercia and the Dane law. This division must have been rapidly fading by that time, for under the strong rule of the Norman kings the power of the central government was increasing; by the time of Henry II (1154-89) it was clear that there was going to be a "common" law throughout England, administered by the new royal judges of the king's court (*curia regis*). Owing to the relative strength and efficiency of royal justice, the common law gradually swallowed up its early rivals, the old local customary laws.

**Influence of Roman and Canon Law.**—The nature of the new common law was at first much influenced by the principles of Roman law, but later it developed more and more along independent lines. The Normans had introduced into England many of the new collections of the church's canon law; many of the early royal judges were themselves clerics, and as canon law was largely based on Roman law (*q.v.*) England was brought for a time into the Roman-law atmosphere. Roman law supplied the early English lawyers with the necessary framework of legal concepts within which to develop their own system. The earliest rules of the common law were thus based partly on an amalgamation of local customs, partly on Roman law and partly on the policy of the central government.

**Importance of the Inns of Court.**—As the law became not only "common" but also more complex, there grew up a body of professional lawyers who gave expert advice to their clients and also supervised the professional education of those who aspired to fol-

low them. These common lawyers had to decide how legal professional education was to be organized in the future. The canonists and the civilians (as Roman lawyers were called) looked to the universities to teach and train new entrants to the profession. While common lawyers were themselves mostly clerics there was a strong temptation for them to follow this course. But the clerical element declined, and by c. 1300 English common lawyers had ceased to frequent the universities and had undertaken their own education in their "inns of court" (*see* INNS OF COURT AND CHANCERY). The result of this was to make the common lawyers still more conscious of the peculiarities of their own developing system, which had now taken on a life of its own. They became more critical of the theories of the Romanists and canonists. A popular exposition of this attitude was the tract *De laudibus legum Angliæ* ("Praises of the Laws of England"), an early example of comparative law written c. 1470-71 by Chief Justice Sir John Fortescue.

The separatism of the common law was fostered by the way it was administered in the independent "common-law courts," of which there were, by the end of the 13th century, three: the court of common pleas, the exchequer (*q.v.*) and the king's bench (*see* also QUEEN'S BENCH, COURT OF). The bench and bar of these courts were staffed by practitioners bred in the inns of court and nourished in the traditions of the common law. The principal subject matter of that law in the middle ages was land law and criminal law, in both of which the crown was deeply interested. A series of new procedures was evolved for each, in which the principal role was played by the jury, a new form of an institution which had its roots in Anglo-Saxon and Frankish law. However, although the common law expanded rapidly between the 12th and 15th centuries, many other quite separate legal systems and jurisdictions coexisted with it. The laws of the church governed marriage and succession, and the clerics had their own internal discipline with many privileges and immunities which often put them beyond the reach of the common law. The Jewish community was governed by a special sort of mixed court. The merchants had their own separate courts, which administered speedy justice under the mercantile law. The law of ships and the sea was administered from at least the mid-14th century by the courts of admiralty, held in the name of the lord high admiral; and there were several special jurisdictions assumed by royal officials such as the steward. Over the centuries, the common law either restricted or annexed many of these rival fields of law.

**The Rise of Chancery.**—By the end of the 14th century the common-law courts were firmly established as the principal organs of royal justice. In earlier days they had exercised a wide jurisdiction in framing and applying the rules of the common law. Now their most creative period was over; the common law was much less able to meet the needs of justice by supplying new remedies for new cases. A large body of rules, many of which were highly technical and artificial, had come into existence, and the common law was increasingly rigid and inflexible. Inevitably, this resulted in many failures to do justice, for in their insistence on the letter of the law the courts often failed to do "equity" between the parties. Another cause of dissatisfaction was that, with the growing political chaos of the 15th century, "over-mighty subjects" could frustrate the ends of justice by bribing or intimidating juries and defying court orders.

**Origin and Nature of the Chancellor's Jurisdiction.**—It had always been possible, in cases where the law could not or would not do justice, to petition the king to exercise his extraordinary legal powers as the "fountain of justice." The fact that he had established the common-law courts to administer the law on his behalf did not mean that he had exhausted his judicial powers, which were theoretically limitless. It was the practice to refer such petitions to the lord chancellor, who, as "keeper of the king's conscience," was the appropriate officer for this duty. During the 15th century the chancellor built up his own court in the chancery for dealing with these cases where the common law was inadequate. Unlike the common-law judges, the chancellor was concerned primarily with the moral concept of "equity" rather than with strict legal rights, the more so because, until the 16th century, chancellors

were almost invariably clerics. In the exercise of his equitable jurisdiction the chancellor was not bound by precedent, as the common lawyers were. He had very wide powers to do justice as he thought fit, and he exercised them with a minimum of procedural formality. The chancery was relatively cheap, efficient and just; during the 15th and 16th centuries it developed spectacularly at the expense of the common-law courts. Equity, as it came to be called, was a fertile source of new remedies and legal concepts. Perhaps the most important of these was the use or trust (*q.v.*), which was an obligation to hold property on behalf of another. The common law would not enforce this obligation, but equity would. For this reason, equity captured for itself a large part of the subject of real property.

**The Struggle With the Prerogative Courts.**—Most European countries during the 16th century were experiencing the rediscovery and "reception" of Roman law, and this influence extended to England. The strong and relatively secure rule of the Tudors was favourable to the establishment of a whole new range of courts, of which the chancery was only one (though the greatest), which for one reason or another owed little to the common-law heritage. An example of these prerogative courts was the court of requests, a poor man's court, which dealt with small claims. Another was the famous and later notorious star chamber (*q.v.*), which dealt primarily with offenses against public order. The common-law courts lost a good deal of business to the chancery and the other new courts, and bitterly opposed the extension of their jurisdiction. One of the principal defenders of the common law was Sir Edward Coke (*q.v.*), perhaps the greatest of all common lawyers. He was a voluminous writer with an immense knowledge of the law. As chief justice of the common pleas (1606–13) and, later, chief justice of the king's bench (1613–16), he waged ceaseless war, first on the chancery court and then against the royal power of James I. He was finally dismissed from the bench in 1616 for his "turbulent carriage," after which he went into parliament and joined the antiroyalist faction. The new courts, indeed, were particularly associated with the royal prerogative, which during the 16th and early 17th centuries was more and more frequently asserted. The common-law courts, on the other hand, were already thoroughly institutionalized and had nothing to gain from changes in the political structure, especially changes which brought new and rival courts with them. Thus, in the 17th-century struggles between king and parliament, the chancery and the prerogative courts were ranged on the side of the king, while the common lawyers on the whole allied themselves with parliament. It was at this period that the tradition of the common law as a bulwark against the arbitrary power of the crown first appeared. The victory of parliament saw the end of the prerogative courts, and the unpopular chancery court only barely survived.

**Influence of Common Law Upon Equity.**—This position was unchanged by the Restoration (1660). However, by that time equity had already received a strong infusion of common-law principles and methods. After the appointment of Sir Thomas More in 1529, chancellors had increasingly been laymen drawn from the ranks of the common lawyers. Gradually the office of chancellor had become more judicial in its character, though it still carried with it great political power. This tendency increased after the Restoration. Only professional lawyers were appointed, and they bent themselves to the task of making equity into a logical and consistent body of rules which would supplement the common law rather than conflict with it. Heneage Finch, later earl of Nottingham, lord chancellor from 1675 to 1682, who has been called the father of modern equity, was instrumental in removing the arbitrary element from equity and emphasized the importance of precedent in chancery decisions. The introduction of equity doubtless enriched the English legal system and in some ways stimulated the growth of the common law; but it created the serious disadvantage of having two different systems—law and equity—administered in separate courts and often impeding each other with such weapons as writs of prohibition and common injunctions. The common law never succeeded in swallowing up equity, but it gradually subsumed most of the other separate jurisdictions. In

the 18th century it absorbed most of the mercantile law. Since the great fusion of jurisdictions by the Judicature act of 1873, common law and equity have been administered in the same courts; but they are still separate bodies of rules, each with its own characteristic methods and remedies.

**Common Law and Statute Law.**—Legislation is another source of law to which the common law had to adapt itself. Although to medieval philosophers it was a difficult question whether man could "make" law *ab initio* instead of declaring existing law, legislation was used in practice by English kings after the Norman conquest. It was, however, relatively rare; and legal development in the middle ages was mostly left to the common lawyers. Early forms of legislation can only be surmised, but from c. 1100 the royal charter became the usual medium, until it was slowly replaced by the statute, cast in forms evolved by the newer institution of parliament. The volume of legislation has steadily increased until, in the 19th and 20th centuries, it has become a vast flood. It was by no means clear at first whether a statute could override a rule of the common law. This was determined at the Reformation, when Henry VIII's use of parliament to effect a fundamental alteration in the position of the church finally exalted the power of parliament over all other English institutions. Although as late as the 17th century common-law judges occasionally claimed that where a statute was contrary to reason or natural justice, it would be void at common law, it has long been clear that in England the courts can do nothing with an act of parliament except apply it. In England always, and normally throughout the common-law world, legislation is superior in strength to common law.

**Distinctions Between Common Law and Civil (Roman) Law Systems.**—The common law has been exported into most of the countries where the English have settled or governed. As subjects of the crown, English settlers carried it with them wherever they went. The end of British rule has not usually involved the abandonment of the common law, though of course it has developed independently thereafter. Today a large portion of the world is governed by one branch or another of the common law. The United Kingdom and its colonies, the United States, Canada, Australia, New Zealand, Ghana, Nigeria and India are all common-law countries in this sense. Though individual rules of law may differ, their legal systems have in common the characteristic hallmarks of the common law. Prominent among these are the institution of the jury, the right to speedy trial and the tradition of a powerful and independent judiciary. Such common-law countries are to be compared with civil-law (*q.v.*) countries such as France, Germany and Italy, which derive their legal systems mainly from Roman law. Perhaps the feature of the civil-law system which is most different from that of the common law is that in civil-law countries the main rules are normally embodied in a legislative code. The common-law judge, however, is normally guided not by a code but by the principles declared in the reports of previous decisions by his predecessors in similar or analogous cases. This system of precedent, fundamental to the common-law method, results in a continuous process of legal evolution which makes for both stability and flexibility, qualities which are essential in any legal system.

**COMMON ORDER, BOOK OF**, sometimes called the Order of Geneva or Knox's Liturgy, a manual of public worship in the Reformed Church in Scotland. The name is still used in some Reformed churches for their service books. A book of "common order," as contrasted with a book of "common prayer," aims at securing a common pattern of worship without making specific verbal forms compulsory, and the prayers are almost entirely put into the mouth of the minister, in accordance with a practice introduced by Calvin, who thought that I Cor. xiv, 16, demanded this procedure apart from congregational amens.

In 1557 the Scottish reforming lords prescribed the use of the

English Book of Common Prayer in place of the Roman missal. Meanwhile, at Frankfurt a controversy had arisen among British refugees between upholders of the English liturgy and others who, under the leadership of John Knox, desired a form of worship like Calvin's. The latter party drew up a liturgy based on Calvin's *La Forme des prières*, but its use was denied and Knox was banished from the city. In 1556, after some revision, the book was put into use in Geneva when Knox became minister of the English congregation there. It is notable as being the first Reformed rite in English and as providing a liturgy ready to hand for the Scottish Reformers, who adopted it after the Reformation in 1560. The norm of public worship followed in the book is the ancient service of word and sacrament.

The policy of the Stuart kings was to adapt Scottish church life to English ways. Their efforts were directed particularly toward introducing bishops into the Presbyterian system and imposing English liturgical forms. An attempt made by Charles I in 1637 to introduce a liturgy prepared by Archbishop William Laud and some Scottish bishops on the basis of the English book brought Scottish resistance to a head. The resulting uprising of the Covenanters (*q.v.*) was inspired less by resistance to episcopacy and prayer books as such than by resistance to royal interference with the freedom of the church. But it led both to a hardening of attitude against bishops, who were regarded as agents of the king, and to greater sympathy with those Puritans who desired books to be less prominent in worship. Up to this time Scottish sentiment was against the extremer forms of Puritanism, and the Book of Common Order had retained the use of the Creed, the Gloria and the Lord's Prayer. In 1645 the Scottish general assembly accepted the Directory of Public Worship, which had been prepared by the Westminster assembly in pursuance of its purpose to unify the church life of England, Scotland and Ireland along Puritan lines. Though the Directory contained full prescriptions as to the content and order of the prayers, it did not pretend to be a liturgy, and required that each minister be careful "to furnish his heart and tongue with further and other materials of prayer and exhortation, as shall be needful upon all occasions."

The subsequent period in Great Britain was one of decline in the manner of worship, not only among Presbyterians. A newer day dawned in Scotland in 1865 with the formation of the Church Service society, which in 1867 produced an influential service book, *Euchologion*. Since that time, most Reformed churches have undergone a revived interest in liturgy and have published books that have largely superseded the Westminster Directory. The Church of Scotland has a scholarly Book of Common Order (1940) that carries further the achievements of several previous books, and the Book of Common Worship (1946) of the Presbyterian Church in the U.S.A. is notable for its much-extended element of common prayer (*i.e.*, prayer voiced by the people).

**COMMON PLEAS, COURT OF**, an English court of law that originated from Henry II's assignment in 1178 of five members of his council to entertain pleas involving contests between individuals, as distinguished from litigation to which the crown was a party. This group of councilors did not immediately emerge as a body distinct and separate from the *curia regis*, or "king's court." It remained a part of the court and traveled with it until art. 17 of Magna Carta (*q.v.*) required that this jurisdiction be assigned to a body to be convened at a designated place, at which time it settled in Westminster hall, London. In 1223, on the majority of Henry III, the court began to maintain separate rolls and in 1272 it was given its own chief justice. Its identity is usually dated from that time.

During the middle ages, common pleas was the busiest though not the highest of the common-law courts; it included within its jurisdiction not only almost all civil litigation but supervision of local and manorial courts as well. Its judgments, however, were subject to review by the court of king's bench (*see* **QUEEN'S**

**BENCH, COURT OF**). Beginning in the 15th century, common pleas engaged in a contest with the court of king's bench and the court of the exchequer for common-law business. The result was an accumulation of complicated and overlapping jurisdictional rules. By the 19th century the multiple forms of writs and competing jurisdictions had become unbearable and the Judicature act of 1873 resulted in a replacement of the three common-law courts, as well as the assumption of equity jurisdiction, by the supreme court of judicature, a single integrated court that remains today as the court of general jurisdiction in England and Wales. *See also* **COURT**. (P. B. K.)

**COMMON PRAYER, BOOK OF**, contains the liturgy appointed by law for use in the Church of England. It is a product of the English Reformation and its successive revisions reflect the phases through which that Reformation has passed.

Before the Reformation the services of the English church were in Latin and followed the local "uses" or modifications of the Roman rite, the pattern liturgy for the greater part of Western Christendom. The chief English uses were those of Hereford, York and Salisbury, or Sarum, the last being the best known and the most widely followed on the eve of the Reformation. Although the uses differed neither from each other nor from the Roman rite in type, they exhibited considerable differences in detail, with the consequence that there was no uniformity of liturgical observance within the single area of the kingdom.

Each use had its own set of service books. A number of these was necessary for the performance of the services and was provided, according to law, at the expense of the parish. The minimum requirement was a *Directorium* (sometimes called *Ordinale* and to be distinguished from the book of ordination rites later attached to the Prayer Book) which indicated the service to be recited on any Sunday or festival in accordance with the variations of the ecclesiastical year (the *Directorium* was also commonly termed the *Pica* or *Pie*, *i.e.* "magpie," because it was printed in black and had no rubric, or red, type); a missal, which contained everything necessary for the celebration of Mass, the principal act of worship; a processional, in which were to be found the psalms, anthems and hymns to be sung in the procession before Mass and after evensong on Sundays and festivals; a breviary, which contained the priest's daily canonical office; and a manual, in which were collected the "occasional offices" or services of baptism, marriage, burial, etc. The services performed by the bishop, *i.e.*, confirmation, ordination, etc., were collected into his pontifical. Mention must also be made of a quasi-liturgical and vernacular prayer book used by educated lay people and known as the primer. This consisted of the Offices of the Dead and of the Blessed Virgin Mary, derived from the breviary with the litanies and other devotions in the vernacular from the 14th century onward, which lay people recited either privately at home or in groups in church during the celebration of the Latin service by the priest and choir. The primer played some part in preparing the way for the Prayer Book.

The introduction of vernacular liturgy and the simplification of reform of church services were among the early changes effected by the Reformation on the continent. In England the approach to liturgical change was slower and gradual. Thomas Cranmer, shortly before becoming archbishop of Canterbury in 1533, had had experience of Lutheran vernacular worship in Germany. More than a decade passed before he had an opportunity of experimenting at home. In 1544 he was authorized by Henry VIII to compile an English litany for use as a "common prayer of procession." The main sources of Cranmer's litany are the litanies in the Sarum processional and manual and Luther's Latin litany of 1529. Some phrases and the final prayer being derived from the Greek liturgy of St. John Chrysostom. Cranmer's first essay at liturgical composition for public use exhibits the same dignity of English style and the same felicitous handling of older material which distinguish his prayer books. With some changes, Cranmer's litany has remained in use to the present day. It was designed to be the first installment of an English processional, which, however, was never completed, Henry VIII being disinclined for further liturgical experiment. In fact the litany of 1544 was the first install-

ment of the Book of Common Prayer.

The second installment followed four years later when, on account of Edward VI's minority, the government of the kingdom was in the hands of a protector and council resolved on reform and Cranmer, himself a member of the council, was no longer restrained by royal conservatism. The order of the Communion, issued in 1548, was a move in the direction of an English Mass. It consisted of devotions in English to be said at the administration of Holy Communion in the course of the Latin Mass; it also ordained the ancient practice, revived in the Reformed churches of the continent of Europe, of delivering to the communicants the cup as well as the bread. The contents of the order—viz., exhortations, invitation to communicate, confession and absolution, "comfortable words," "prayer of humble access" and sentences of delivery—were to reappear in the Prayer Book. With the exception of the prayer of humble access (which may be attributed to Cranmer) the order owes its inspiration to a German church order compiled in 1543 to forward the Reformation in the diocese of Cologne.

**First Prayer Book (1549).**—The royal proclamation promulgating the order of the Communion gave warning of "the other order" to come. The "other order" was the first Prayer Book enacted by the first Act of Uniformity in 1549. By ordaining that "all common and open prayer" should be conducted "in such order and form as is mentioned in the said book, and none other or otherwise," the act suppressed the local uses and their Latin service books. Henceforward the realm would have but one use, and the Prayer Book would be its service book. The comprehensive character of the book is demonstrated by its table of contents, which with some rearrangement has passed to its successors. The services have been collected from the several Latin service books into a single volume comparable with such Lutheran Church orders as the *Agenda* of Saxony and the *Kirchenordnung* of electoral Brandenburg, both issued in 1540. The preface of the Prayer Book—although primarily concerned with matins and evensong, the substitute for the breviary (and largely paraphrased from Cardinal Francisco de Quiñones' Latin preface to his revised Roman breviary of 1535)—expresses the principles which motivate the book as a whole. The fundamental principle is intelligibility. Services must therefore be in English and must be so simplified that there shall be no need of the complicated rules of the *Directorium* or *Pie*. Further, psalms and lessons must be read in sequence without frequent interruption by "proper" psalms and lessons appointed for festivals, as in the Latin office. Similarly, the sequence of psalms and lesson in a service must no more be broken by antiphons to the psalms and responds after the lessons; and the psalms were in fact issued separately, as *The Psalter or Psalms of David*, in Aug. 1549. Again, only "the very pure worde of God, the holy scriptures," and the books of the Apocrypha may be read; the lives of the saints hitherto read on their festivals and other nonbiblical writings were jettisoned. The resultant jejune order is described as "much agreeable to the mynde and purpose of the olde fathers" who instituted daily service.

The first Prayer Book preserves much of traditional liturgical form and usage. The principal rite, "commonly called the Masse," is modeled on the Latin Mass. The canon, or central prayer in which the elements are consecrated and Christ's passion, resurrection and ascension commemorated, is reminiscent of the Latin canon, partly in form and partly in content. The sentences of delivery (which are the first half of those now in use) refer to Christ's body and blood. The traditional vestments and wafer bread are retained. At baptism the water is blessed; and the infant is exorcised before, and anointed with chrism and clothed with the white robe (chrisom) after, being baptized. At confirmation the bishop marks the child's forehead with the sign of the cross. At the visitation of the sick, the sick person may be anointed with oil, and Holy Communion be brought to him from the church, if he so wish. The traditionalism of the book is of a Lutheran type, however, and is offset by Reformed elements which are equally characteristic of the book. The primary title of the Mass is "the Supper of the Lorde, and the Holy Communion." The celebrant, at his choice, may wear a cope instead of a chasuble.

There may be no celebration of the service, "except there be some to communicate with the priest." This restriction, together with the title and the ample devotions of the order of 1548, implies that the rite is of no significance apart from Communion. In the absence of communicants the priest is to follow Lutheran usage and to read only the ante-Communion part of the service. A non-Lutheran Reformed feature is the prohibition on elevating wafer and chalice after their consecration. In regard to the controversial matters of the real presence of Christ's body and blood and of the conception of the Mass as a propitiatory sacrifice for living and dead, the service of 1549 is equivocal. Cranmer (whose authorship of the service, and of most of the book, is indisputable) declared its meaning to be Protestant. His conservative opponent, Stephen Gardiner, bishop of Winchester, argued that the phraseology of the canon and the inclusion within the canon of prayer for the dead justified a Catholic interpretation.

**Second Prayer Book (1552).**—In 1552 a second Act of Uniformity substituted the second Prayer Book for the first. The second book is a radical revision of its predecessor, designed to align English worship with the more extreme Reformed position to which Cranmer now adhered. Almost all the traditional usages of the first book are jettisoned. Alb, chasuble and cope are forbidden; bishops are to wear rochets, other ministers surplices only. The altar is replaced by a movable Communion table. The Communion service has been so rearranged that it no longer follows the order of the Mass, and the word "Mass" is no longer applied to it. The canon has been broken up; the commemoration of Christ's passion, etc., and the prayer for the dead have been discarded; and the remaining parts have been inserted at new positions in the service, thus rendering it insusceptible of Gardiner's interpretation. The idea and term of "consecration" of the elements is avoided. The present "prayer of consecration" made its first appearance in the second Prayer Book; but in 1552 it lacked a title and also the directions to take bread and cup, etc. The bread used may be domestic instead of wafer. The new sentences of delivery (which are the second half of those now in use) exclude reference to Christ's body and blood; and the phraseology of the prayers of humble access and of thanksgiving (after reception) has been so revised as to avoid implying that the elements are the means of conveying Christ's body and blood to the communicant. The total effect of these changes is to transform the liturgical action into eating of bread and drinking of wine in thankful remembrance of Christ's death. The declaration on kneeling, or "black rubric," which was attached to the Communion service by order of the council after parliament had enacted the second Prayer Book, affirms that kneeling at reception does not imply that any adoration is done either to the sacramental elements, or to any supposed "reall and essentiall presence there beeyng of Chrystes naturall fleshe and bloude," which are stated to be "in heaven and not here."

The service of baptism has been as drastically revised as that of the Communion, although without a corresponding change in its meaning. The exorcism, the blessing of the wafer, the anointing with chrism and the robing with the chrism are discarded. The central portion of the service has been redrafted so as to present a parallel with the equivalent portion of the Communion service; i.e., recalling of the institution (Matt. xxviii, 19), administration of the sacrament, the Lord's Prayer and the prayer of thanksgiving. The infant is now to be marked with the sign of the cross immediately after being baptized. The book allows no other use of the sign of the cross.

The second Prayer Book had been in force for little more than six months, when the accession of Mary in 1553 brought back the Latin rite. The Prayer Book was used, however, in the churches of English Protestants who migrated to the continent in Mary's reign. There is some evidence to suggest that when Elizabeth succeeded Mary in 1558 there was a project to restore the first Prayer Book. In the issue, less conservative influences prevailed; and the Prayer Book actually restored was the Prayer Book of 1552, exclusive of the "black rubric." With additions and alterations, important if generally slight, the second Prayer Book has remained in force since its restoration by the third Act of Uniformity in 1559.

The same act made the first of the important additions: it provided that, in the Communion service, the sentences of delivery of 1549 should be added to those of 1552, the former taking first place. The doctrinal implication of the addition is significant; reception of Christ's body and blood was again associated with reception of the sacramental elements. When the book was published it was found to contain an important change in the ornaments rubric, or direction concerning the vesture of the ministers. The altered form of the rubric directed the minister "at the time of the communion" to use the ornaments which "wer in vse by auctoritie of parliament in the second yere of the revgne of King Edward the VI" and thus legalized the vestments of 1549. The alteration was not covered by the Act of Uniformity, but was presumably authorized by the queen. The Mass vestments were discontinued; but copes were worn over rochets and surplices in most cathedrals and in the queen's chapel, where the Communion table, dressed altarwise, stood unmoved at the east end, and where, also, wafer bread was retained.

Controversy with both papists and Puritans over the Communion service led to the reassertion of the idea and practice of consecration. There being no direction in the Prayer Book, the court of high commission in 1573 ruled that a second supply of bread and wine, before being distributed in Communion, must be "consecrated" by Christ's words repeated over it in a second recital of the liturgical institution-narrative.

The trend of return to the standard of 1549, noticeable in the official interpretation of the service of 1559, was confirmed by the teaching about the Lord's Supper contained in the questions and answers concerning the sacraments added to the catechism, by authority of James I, in 1604. The same trend is observable in the ill-fated Scottish Prayer Book of 1637. This book, often wrongly styled "Laud's liturgy," was a revision of the English book undertaken by Scottish bishops in the hope of reconciling Scottish Presbyterians to the use of the Prayer Book. The Scottish was the first Prayer Book to introduce the description "the prayer of consecration" into the Communion service. The description, and the Scottish directions both for an additional consecration and also for the reverent treatment of any consecrated bread and wine remaining after the distribution, were to be adopted by the English revisers in 1661.

**Revisions of the Prayer Book.**—The English Prayer Book, which had been the object of Puritan attack for three-quarters of a century, was "abolished" by parliament in 1645. On the restoration of Charles II in 1660, the Prayer Book was also restored and in the year following a conference between bishops and Presbyterian divines was held at the Savoy palace in London to consider Presbyterian wishes for revision. The conference failed and the work of revision was committed to the convocations. The result was conservative. The substance of the old book remained unchanged. The principles of the revision, as expressed in the new preface, were the "better direction of them that are to officiate"; removal of archaisms; clarification of ambiguities; and the addition of new prayers required by new circumstances. Some of the new features met the wishes of the Presbyterians; e.g., the use of the Authorized Version for all lessons and biblical quotations, the attachment of the doxology to the Lord's Prayer on several occasions, the restoration of the black rubric in slightly amended form and the reintroduction of a blessing of the water at baptism. The revised book was enacted by the fourth Act of Uniformity in 1662. "Sealed books" (i.e., copies of the new book printed exactly from the manuscript annexed to the act, and authenticated by the great seal) were sent to the cathedrals of England and Wales to ensure preservation of the standard text.

A further revision, aiming at a reconciliation between the established church and nonconformists, was moved in 1689, but came to nothing. Again, in 1906, following upon the "ritual" disputes of the previous half-century, the convocations were authorized to revise the book in such a way (according to the royal letters of business) as "to secure the greater elasticity which a reasonable recognition of the comprehensiveness of the Church of England and of its present needs seems to demand." Ill-conceived features and unacceptable regulations for reservation of the sacra-

ment, purporting to satisfy the desires of the Anglo-Catholic party, provoked opposition from Anglo-Catholics and Protestants alike. The convocations and the church assembly passed the revised book in 1927. In parliament, however, though passed by the house of lords, it was rejected by the house of commons. Modified in regard to the reservation regulations, it was again presented to parliament in 1928, and again rejected by the commons. The official liturgy of the Church of England retains the form given to it in 1662; but considerable latitude in the use of the book everywhere obtains. (See also ENGLAND, CHURCH OF: 20th-Century History and Development: Prayer Book Revision.)

**Ordinal.**—The book containing the rites for consecrating bishops and ordaining priests and deacons was not counted a part of the Prayer Book until 1662. It preserves something of the pattern of the Latin rites, but its content has been influenced by the German reformer Martin Bucer. Ordination to each order consists in the laying on of the ordaining bishop's hands accompanied by a formula. The formulas for bishops and priests begin with the words, "Receive the Holy Ghost," retained from medieval usage. From the same usage the formula for priests also retains the clause, "whose sins thou dost forgive, they are forgiven," etc. The act of ordination both of bishops and priests is preceded by prayers which are almost identical and are derived from Bucer's ordination prayer. The first ordinal, issued soon after the first Prayer Book, retained the medieval *porrectio instrumentorum* in the form of delivering to priests a chalice and a paten with bread, as instruments symbolical not of offering sacrifice, as in the Latin rite, but of ministering the sacraments. The delivery of a pastoral staff to bishops, in symbolism of their function as shepherds "to the flock of Christ," was also retained. The first ordinal introduced the delivery of the New Testament to deacons and of the Bible to priests and bishops as instruments of the preaching ministry. The revised ordinal of 1552 discontinued the delivery of chalice and paten and of the staff, retaining only the scriptural instruments. A further change was made in 1661. The ordination formulas of both bishop and priest had neglected to specify the order being conferred. In order to meet papist criticism of the omission and to silence the Presbyterian argument that the prayers and formulas of the ordinal witnessed to the fundamental parity of the two orders, the revisers of 1661 redrafted the two formulas, in each case specifying the order conferred and so asserting a distinction between bishop and priest.

**Related Prayer Books.**—Most churches of the Anglican Communion now possess their own variants of the English Prayer Book. The Scottish book of 1637 was not reintroduced at the Restoration, but its Communion office was used in some Episcopalian congregations and private chapels. Under Nonjuring influence, during the first half of the 18th century, it became the practice to rearrange the several parts of the office in accordance with the Eastern pattern; i.e., the invocation in the consecration prayer was removed from its position before the institution narrative to a subsequent point of the prayer, and the general prayer for the church was placed after the consecration prayer. This arrangement received the approval of the Scottish bishops in 1764. The "Scottish liturgy" or Communion office of the present Scottish Prayer Book (1929) retains the Eastern pattern.

The Scottish Communion office of 1764 is also associated with the beginnings of the Prayer Book of the Protestant Episcopal Church of the United States of America. At the time of his consecration by Scottish bishops in 1784, Samuel Seabury, the first American bishop, undertook to promote the use of the office among American Episcopalians. In 1789, however, the general convention, which determined the form of the first American Prayer Book, while retaining the Scottish consecration prayer with some modification, left the general prayer for the church in the English position. The Communion office contained in the American Prayer Book of 1928 preserves this compromise, but in certain other respects has reverted to Scottish usage.

In 1954 the Church of the Province of South Africa issued a revised Prayer Book of which the distinctive feature is the Communion service drawn up about 30 years earlier as an alternative to the English service. In the main this service follows the Scottish

pattern of 1637; but the consecration prayer adopts ancient Roman phraseology for expressing the eucharistic offering, and at the same time introduces an invocation of the Holy Spirit, in accordance with Eastern usage, after the offering.

In 1959 the Anglican Church of Canada issued *A Draft Prayer Book* for experimental use over a period of years. The consecration prayer of the draft Communion service may be described as a modification, under slight South African influence, of the Scottish prayer of 1637.

The variant Prayer Books referred to here and including the Irish (1927) and the Indian (1957), although providing for new needs and local requirements, exhibit a clear continuity with the English book of 1662. Nevertheless it will have been observed that in the matter of the Communion service (with the exception of the Irish book, which preserves the English service unchanged) the variants prefer Cranmer's first service, in some Scottish modification, to his second.

The fine diction of the Prayer Book, and the beauty of expression which marks its prayers, have led to the adoption of many of its prayers into the liturgies of English-speaking churches outside the Anglican Communion (e.g., into the Book of Common Order of the Church of Scotland and that of the United Church of Canada).

**COMMONS, JOHN ROGERS** (1862–1945), U.S. economist, authority on labour and author of reform legislation in Wisconsin, was born at Hollandsburg, Darke county, O., on Oct. 13, 1862. He studied at Oberlin college and at Johns Hopkins university, and joined the faculty of the University of Wisconsin in 1904. Commons first achieved a reputation as the foremost authority on U.S. labour. With the collaboration of disciples, he published *A Documentary History of American Industrial Society* (10 vol., 1910–11) and *History of Labour in the United States* (4 vol., 1918–35). Although subject to considerable controversy, Commons' theory of the evolution of the American labour movement in terms of changes in the market structure became the leading theory.

After World War I he broadened his reputation with *Legal Foundations of Capitalism* (1924) and its sequel, *Institutional Economics* (1934). These studies stressed the importance of group controls or rules as the bases for the orderly expansion of individual action. He especially emphasized the role of the U.S. supreme court as the "supreme faculty of political economy."

Commons drafted much of the reform legislation that made Wisconsin the laboratory for other states and the federal government, notably legislation on civil service, public utilities, workmen's accident compensation and unemployment insurance. These activities made him as influential a factor in economic practice as in theory. He died May 11, 1945.

For Commons' bibliography, see his *Economics of Collective Action* (1950), and Joseph Dorfman, *The Economic Mind in American Civilization*, vol. 3, ch. 8 (1949) and vol. 4, ch. 13 (1959); for biographical material see Commons' autobiography, *Myself* (1934). (J. DN.)

**COMMONS**, a word used to describe the rights of persons to enjoy a profit a prendre in common and, more generally, to describe the land over which those rights are enjoyed.

By the common law, a profit a prendre (or, more shortly, a profit) is the right to take from the land of another either part of the soil or its produce, or the wild animals existing on it. Thus a right to "hawk, hunt, fish and fowl" may exist as a profit, and so may the right to take grass, herbs or minerals. A profit enjoyed by one person to the exclusion of others is called a several profit, whereas a profit enjoyed in common with others is called a profit in common, or simply a common.

**England.**—Commons originated in the medieval system of cultivation of lands in England. Each vill or township was surrounded by the arable land, cultivated in strips by each householder, by meadows and pastures, and by the waste. From this waste each householder was entitled to take wood for repairs and fuel. When the fields were under crops and the meadows laid up for hay, the waste was used to support the horses and oxen needed for the plow, and the cows and sheep, who contributed their manure. Each householder then had the right to turn out his beasts to graze on the waste; and in the developed terminology of the law, these rights were profits in common, exercisable over the waste, or common.

**Types.**—Any type of profit may be held in common. There are five main categories. A common of pasture is perhaps the most frequent; it confers the right to take away the grass and herbage by the mouths of cattle. Often the cattle are limited to the number levant and couchant on the land of the commoners; i.e., the number which their other land is capable of maintaining during the winter. The common may, however, be *sans nombre* ("without stint"), though even here the number is limited to the amount the common is capable of maintaining. A common of turbary gives the right to take peat or turf for use as fuel in the commoners' houses. A common of estovers entitles the commoners to take wood as housebote, for repairing their houses or burning in it; as plowbote, for agricultural implements; and as haybote, for repairing fences. Commons of piscary or other sporting rights entitle the commoners to take fish, game and fowl; and a common in the soil gives the right to take sand, gravel or minerals. In general each type of common may exist as appurtenant, appendant or in gross. A common appurtenant is granted for the benefit of nearby land of the commoner, and passes with that land. A common appendant is similar, except that it can only exist in land forming part of ancient manors. A common in gross is held independently of any other land. Commons may arise under statute, by operation of law, by express or implied grant or by long enjoyment.

**Approvement.**—After the Norman conquest it became established that title to the waste was vested in the lord of the manor, subject to the commons owned by the householders. This soon gave rise to conflicts of interest which took six centuries to resolve. The Statute of Merton, 1235, and the second Statute of Westminster, 1285, confirmed the lord's right to "approve" (i.e., take for his separate use) any of the waste, provided he left enough for all the animals that the commoners were entitled to turn out upon the common; the onus of proving sufficiency lay on the lord. Approvement was by no means always against the public interest, for it often resulted in the cultivation of land that otherwise would have lain derelict; but sometimes the right was merely used to give the lord a new deer park or the like. With the decay of the old system of agriculture, and the great increase in population in the 19th century, approvement was subjected to control by the Commons act, 1876. Under this act a person seeking to approve a common otherwise than under the act must advertise his intention in the local press on three successive occasions. The Law of Commons Amendment act, 1893, prohibited approvement except with the consent of the minister of agriculture, fisheries and food, given after holding a local inquiry.

**Enclosure.**—Enclosure differs from approvement in that the whole of the waste is discharged from all rights of common, whereas approvement discharges only part of the waste, and then only from commons of pasture. In 1709, the first enclosure act was passed, and by the second half of the century more than 40 enclosure acts were being passed each year, each act authorizing the enclosure of specified areas of land, ostensibly for encouraging the more efficient production of food. The Inclosure (Consolidation) act, 1801, facilitated enclosures by enacting a series of common-form clauses which could be incorporated in individual enclosure acts, leaving only the general question of enclosure or not to be debated; and in 1801 no fewer than 119 enclosure acts were passed, enclosing over 300,000 ac. The Inclosure act, 1845 (as amended by a series of later acts), further aided enclosures

by laying down a procedure under which it became unnecessary to obtain individual acts of parliament. But public opinion was becoming aroused by the disappearance of open spaces, especially in and near London and the larger cities, and the Inclosure act, 1852, prevented any further enclosures being made without the express consent of parliament. The Commons act, 1876, established the modern procedure. An application must be made to the minister of agriculture, fisheries and food. If a prima-facie case is made out, regard being had to the benefit of the neighbourhood, a local inquiry is held. If this establishes the case for an enclosure, a provisional order is submitted to parliament for confirmation.

**The Public.**—The difference between legal theory and popular assumption became especially marked in the case of commons. In law a common was land which was owned by the lord, subject only to the limited rights of the commoners; and only the lord and commoners had any rights over it. In common practice, the rights of the lord and of the commoners kept the land open and accessible to all; and with fewer commoners exercising their rights as the years passed, the public's assumption that a common was so called because it was common to all became more firmly established. Until the Law of Property act, 1925, came into force at the beginning of 1926, the law had given little enough support for this view, though under various statutory powers to make provisions for the regulation of commons, bylaws could be made regarding the use of commons for recreation. However, s. 193 of the act of 1925 gave the public "rights of access for air and exercise" to urban commons, subject to certain limitations. Section 194 extended the restrictions on enclosures to the erection of buildings or fences or any other works which impede access to any common.

**The Modern Position.**—It is difficult to say how much land was enclosed during the century and a half that enclosures were in full spate; one estimate puts it at as much as one acre in every seven in England. Nevertheless, the process was halted just in time; and much of the credit for this must go to a small group of men who afterward formed the Commons Preservation society. The most prominent were George Shaw-Lefevre (afterward Lord Eversley), Henry Fawcett and Sir Charles Dilke. There remain something between 1,500,000 and 2,000,000 ac. of common land in England and Wales. It is capriciously distributed. Thus there is little in the Midlands, whereas in Surrey nearly every parish has its common, and there are large areas of heath and moorland. In some cases, there are still commoners who exercise their rights to pasture their beasts; but gradually these rights are falling into desuetude. In general practice as well as in public estimation, commons are more and more becoming places of recreation for the public, and less and less places where commoners exercise their profits a prendre in common. Enclosures and improvement alike are almost things of the past. The danger that commons might prove attractive targets for land-hungry local authorities with powers of compulsory acquisition has been met by subjecting all such acquisitions to a special parliamentary procedure which requires the proposal to be referred to each house of parliament: see, e.g., Acquisition of Land (Authorisation) Procedure act, 1946, s. 1 (2). In broad terms, commons may be said to have nearly completed their transition and to have attained stability as an institution for the public benefit.

See also ENCLOSURE.

(R. E. MY.)

**United States.**—During the colonial period of American history, commons were prevalent in the New England area. The English manor system of landholding, however, was never a part of the colonial settlements. In Massachusetts, for example, all titles were presumed to be freeholds based upon grants from the crown and free from the feudal incidents of allegiance and duties to the lord of the manor; indeed, there was no manor. Moreover, in the early days land was plentiful in the colonies. In one village 60 families were granted about 64 sq.mi. for their individual and common use. Each family had about one square mile of land, and the families were grouped in the centre of the area for protection against the Indians. The village community enjoyed the use of a large area of common land belonging to the

proprietors, who had a right to sell their individual interests in such land, and it was inherited by the heirs of the owners. While common land was devoted to common use, the settlers had the privilege of pasturage, cutting wood and using other products of the land. It is said that in the Newbury area there were cow commons, ox commons, calf commons and sheep commons.

Perhaps the best known of the New England commons is the Boston common. Its origin is somewhat obscure, but it appears that in 1634 a Rev. William Blaxton (Blackstone) sold a tract of approximately 45 ac. to the town of Boston for £30. Later a royal grant and deeds of purchase from Indian tribes established clear title to this tract. Town records of 1640 show a vote not to sell any part of this land, but to use part of the tract for streets. In its early history Boston common was used to pasture cattle and sheep. In the course of its development from an unimproved parcel of land it became a drill field for local militia. It was used also for training British troops, and colonial soldiers used it in 1775 for encampment on their march to Bunker hill. Other uses included a location for executions, dueling and religious meetings. In the 20th century Boston common is important as a recreation centre where the public may enjoy the usual pleasures of a large park. In 1908 George F. Parkman bequeathed \$5,000,000 to the city of Boston to maintain and improve the area.

**COMMON SENSE** is intelligence of the degree conventionally expected of adult persons in practical affairs. In the history of philosophy, however, the term has had other connotations.

Aristotle, in his *De anima*, book ii, 6, divides the objects of sense between "special objects" (that is, objects discernible to one sense only, as colour is to sight) and "common sensibles" (objects discernible to more than one sense), the latter group comprising movement, rest, number, figure and magnitude; and in book iii, 1, after denying that there is any sixth sense or sense organ to be added to the five natural ones for the perception of common sensibles, he concedes that there is a "general sensibility" that enables us to perceive them directly. With this reference to common sense, which later Aristotelians also called inner sense, means the co-ordinating faculty of the mind.

For other technical uses of the term see COMMON SENSE, PHILOSOPHY OF.

**COMMON SENSE, PHILOSOPHY OF**, the usual designation of the Scottish philosophy of the school of Thomas Reid (1710-96), Adam Ferguson (1723-1816), Dugald Stewart (1753-1828) (*qq.v.*) and others.

This trend of thought was a reaction or revolt against the skepticism of Hume and the subjective idealism of Berkeley, both of which were regarded as the consequences of a false start, namely an excessive stress on ideas, and as reductions to absurdity of the premisses from which they started. For the false start Descartes and Locke were held to be chiefly responsible inasmuch as they gave to ideas an importance that inevitably made everything else succumb to them.

Ideas [says Reid] seem to have something in their nature unfriendly to other existences . . . they have by degrees supplanted their constituents, and undermined the existence of everything but themselves. First, they discarded all secondary qualities of bodies; and it was found out by their means that fire is not hot, nor snow cold, nor honey sweet; and, in a word, that heat and cold, sound, colour, taste and smell, are nothing but ideas or impressions. Bishop Berkeley advanced them a step higher, and found out, by just reasoning from the same principles, that extension, solidity, space, figure and body, are ideas; and that there is nothing in nature but ideas and spirits. But the triumph of ideas was completed by the *Treatise on Human Nature*, which discards spirits also, and leaves ideas and impressions as the sole existences in the universe (*Works*, i, p. 109).

In the actual perception of the normal unsophisticated man, sensations are not mere ideas or subjective impressions but carry with them the belief in corresponding qualities as belonging to external objects. Such beliefs, Reid insists, "belong to the common sense and reason of mankind," and in matters of common

sense "the learned and the unlearned, the philosopher and the day-labourer, are upon a level."

Kant, who was too much under the influence of idealism to respect the philosophy of common sense, the natural enemy of idealism, spoke contemptuously of common sense as "one of the subtlest inventions of modern times, by which the emptiest talker may coolly confront the profoundest thinker, and hold out against him" (*Prolegomena*, Introduction). That, however, did not kill all forms of the philosophy of common sense.

From 1816 to 1870 the Scottish doctrine was adopted as the official philosophy of France; and in the 20th century G. E. Moore's teaching (in particular his "Defence of Common Sense," *Contemporary British Philosophy*, 1925) convinced many British and U.S. philosophers that it was not their business to call in question the common certainties but rather to analyze them.

(A. Wo.; X.)

**COMMONWEALTH** is the term that was often employed by 17th-century writers (e.g., Thomas Hobbes and John Locke) to signify the concept of the organized political community. For them it meant much the same as either *civitas* or *respublica* did for the Romans, or as "the state" means in the 20th century. Specifically, also, commonwealth served as the label of the Cromwellian regime in Great Britain (1649–60). Modern usage has further extended the term. Thus, the Australian colonies were federated as states in 1900 under the official title of the Commonwealth of Australia. Then, as various British colonies evolved from a status subordinate to the United Kingdom into a free association of equal partners, the new relationship was named a commonwealth, especially after the declaration on status approved by the 1926 Imperial conference.

After India became a republic and chose to remain inside the commonwealth, the phrase "head of the Commonwealth" was substituted for "emperor of India" in the royal title, and Queen Elizabeth II was so crowned in 1953.

In the United States, commonwealth has continued to be the official description of four states (Kentucky, Massachusetts, Pennsylvania and Virginia).

The same term also was applied to the island of Puerto Rico after the act of congress of 1950 and adoption of the constitution of 1952.

(L. LIP.)

**COMMONWEALTH OF NATIONS**, formerly known as the British Commonwealth of Nations, is in formal terms a group of sovereign states which recognize the British monarch as head of the Commonwealth, symbolizing their free association with one another, together with their dependencies (colonies, protectorates, protected states, and trust territories).

## I. THE COMMONWEALTH TODAY

On Jan. 1, 1967, the full, sovereign membership of the Commonwealth comprised the United Kingdom, Canada, Australia, New Zealand, India, Pakistan, Ceylon, Ghana, Malaysia, Nigeria, Cyprus, Sierra Leone, Tanzania, Jamaica, Trinidad and Tobago, Uganda, Kenya, Malawi, Malta, Zambia, the Gambia, Singapore, Guyana, Botswana, Lesotho, and Barbados, which meant that there was at least one member in each continent. The one feature which all except Britain had in common was that they had been British dependencies before attaining independence. Their decisions to seek membership in the Commonwealth testified to their wish to maintain friendly relations with Britain. In a practical sense the Commonwealth may be regarded as an answer to the problem of maintaining fruitful connections between new states and their former colonial masters without impairing the sovereign status which the new states have acquired.

Viewing the Commonwealth in this way draws attention to the fact that there were still at Jan. 1, 1967, dependencies which had not attained either independence or the status of full members of the Commonwealth. It was customary to speak of these as within the Commonwealth by virtue of their being dependencies of Britain or another member state; but their transition to full Commonwealth status on attaining independence is not automatic and might conceivably be refused by the existing members if they wished to express disapproval of a new state's regime. Although Britain has exercised a guiding role in the development of the Commonwealth, it is formally an equal of each other member and has no power of veto over what the membership of the Commonwealth may be or what might be decided in its name. The British monarch's headship of the Commonwealth is solely symbolic; it gives the British government no legal control over either the machinery of the Commonwealth or the actions of the other members. At the same time, no member is under formal obligation to follow any "Commonwealth" policy or to submit to control or disciplinary action by other members. The Commonwealth is a free association: members are free to join and leave as they please, and free to adopt whatever lines of policy seem appropriate to them as sovereign states. It is not an abridgment of independence, but a means whereby independent countries can maintain in an informal way the various connections which survived their separation from the sovereignty of the British Parliament.

As an association of sovereign states, the Commonwealth is notable for its lack of a formal constitution (thus distinguishing it from such bodies as the United Nations or the Organization of American States); for its gradual emergence from the organization of the British Empire (see *The Development of the Commonwealth*, below); for its emphasis upon consultation rather than action; and for the stress traditionally laid upon informality in its operations. These characteristics make it much more diffi-

cult to describe than other, more formal, associations of sovereign states. Moreover, it has changed in tone and appearance within a relatively short time. Up to the end of World War II it was essentially an association of white settler countries with Britain. The addition of India, Pakistan, and Ceylon in 1947 and 1948 changed its appearance but not its highly informal character. The great increase in membership in the 1960s, especially resulting from the independence of a number of African states, made more difficult the informality which had previously characterized the meetings of its heads of governments, and brought into being a Commonwealth secretariat which would have seemed alien to its operations in earlier periods. Nevertheless, the Commonwealth's vital elements of free association and lack of formal obligation remained.

**1. Member States.**—The member states of the Commonwealth vary greatly in size, location, population, and culture. Details of their areas and populations will be found in the Tables. The countries also are almost as varied in political organization as in other respects. Before 1949 it was widely assumed that a Commonwealth member would owe allegiance to the British monarch in a direct, domestic sense, and would also be a parliamentary democracy on the British model. Because of the determination expressed by India in 1949 to become a republic and yet remain in the Commonwealth, the first of these conditions was altered. India became a republic, a course which was later followed after independence by Pakistan, Ghana, Nigeria, Cyprus, Sierra Leone, Tanzania, Uganda, Kenya, Malawi, and Zambia. In none of these countries has the British monarch any domestic significance. The older Commonwealth members, such as Australia and Canada, together with some of the newer ones, such as Jamaica, have remained monarchies, in which the British monarch reigns in his or her own person as the head of state of the country in question, being represented for practical purposes by a governor-general who is appointed on the advice of the local government. Malaysia is also a monarchy, but has a head of state elected from among the local sultans for a limited term.

Parliamentary democracy is not now characteristic of all Commonwealth members, although it flourishes in most of them. In others it has been replaced by variants of personal and military rule. Yet it would be fair to say that the parliamentary tradition survives in some respects in these latter countries, where the associated ideals of free courts and a free press are still pursued.

The Commonwealth is neither the sole international association to which its members belong, nor the most important to many of them. It is, however, a useful element in their diplomatic resources.

The areas and populations of the territories of the Commonwealth are shown in Tables I and II. The dates next to the names indicate in some cases when colonies were first organized or claimed as British, in other cases treaties recognizing either British possession, protecting status, or mandatory power.

**2. Functions of the Commonwealth.**—The informal nature of the Commonwealth makes it hard to draw up a precise list of the functions which the Commonwealth performs. There can be discerned, however, certain advantages derived from it by the members as a whole, by Britain, and by the members in their capacity as individual states.

For the members as a whole, the Commonwealth serves the purpose of articulating for discussion whatever common aims they may have. These common aims were easier to identify in the days of smaller membership. Before World War II, they were expressed by successive imperial conferences as the pursuit of peace and of economic prosperity, the first through a degree of common action in defense, the second through assistance in trade, migration, and investment. Since World War II, such common aims have become fewer and more diffuse. But Britain's position as the main provider of external capital to all the other members except Canada has given them a common interest in the stability of sterling as a currency, and at times they have shown a broad agreement in their views concerning world politics. In general the main advantage of the contemporary Commonwealth is that it provides a multiracial forum in which issues which concern the

members can be discussed without the same intensity of publicity and obligation as other international associations command. The framework of consultation and cooperation includes numerous opportunities for informal contacts; the common legacy of the English language and British legal and administrative practice provides something of a basis for discourse. Moreover, since there are few Commonwealth decisions which can be registered as such, and since these are arrived at by consensus rather than by voting, the atmosphere at Commonwealth meetings is often more relaxed than at those of the UN and similar bodies.

For Britain, it is often said that the function of the Commonwealth is to cushion the impact of the loss of empire. Such a statement is acceptable if it is meant to suggest that fruitful connections were not severed when former colonies became independent; it is less so if it is intended to suggest that the British public was lulled into thinking of the Commonwealth as simply the Empire under another name. There has probably been sufficient open disagreement between other Commonwealth members and Britain to make this latter position untenable. However, it can be argued that the very existence of the Commonwealth implies some tribute to Britain's capacity to settle colonial problems peaceably. The British Empire was more varied and widespread than any other colonial system; it was dismantled with less upheaval than the others, and the great majority of former dependencies elected to become members of the Commonwealth. (Those which did not included Burma and a cluster of Middle Eastern states: Egypt, the Sudan, Iraq, and the present constituents of what was formerly Palestine. Eire gave up Commonwealth membership after possessing it in an attenuated form for two decades; South Africa did so in the face of African and Asian criticism of its racial policies.) Britain has presumably gained some prestige from the mere existence of the Commonwealth.

In addition, however, the Commonwealth has provided a formal framework for the numerous contacts which Britain retains with former dependencies. These are most direct in the case of Canada, Australia, and New Zealand, which are largely the products of British migration. Investment, trade, sport, and culture have all created permanent connections with Britain. To a lesser extent, the same is true of other Commonwealth countries. In spite of language and ethnic differences, the modern aspects of the economies and cultures of the African, Asian, and Caribbean members of the Commonwealth owe more to Britain than to any other country. The practical effects are seen in business, trade, banking, technology, education, religion, law, and many other spheres. The Commonwealth states are those on which Britain might be expected to concentrate most attention, simply because they have so much in common with Britain. The Commonwealth provides a framework in which this concentration can be carried on. British people have occasionally suggested that their country pays too much attention to Commonwealth countries and too little to Europe; but it is likely that the Commonwealth will continue to be regarded as a useful means of conducting relations with those countries which, apart from the U.S., the Republic of Ireland, and South Africa, are among the few that speak English as an official language.

The functions of the Commonwealth for the overseas members are all connected with their links with Britain. For the former colonies of settlement, the links are partly sentimental, partly economic, and partly a matter of defense. For the former colonies of administration, especially in Asia and Africa, they are largely a matter of trade and investment, and of the special knowledge which Britain has of their problems. Small, poor countries, such as Malta, the Gambia, and Malawi, would find it hard to exist without the external financial aid provided by Britain. In other cases, chiefly Malaysia and Singapore, there has been measurable gain from British military assistance. In others, such as India and Pakistan, the function of Commonwealth membership has been largely the preservation of existing associations. The fact that Commonwealth members could disagree vehemently and publicly with Britain over such an issue as the Suez crisis of 1956 has meant an easing of what might otherwise have been intolerable strains; if it had been necessary to demonstrate a show of unity within the Commonwealth, this would have been impossible. But,

TABLE I.—Independent Members of the Commonwealth and Their Dependencies (Excluding U.K. Dependencies), 1967

(The independent members are set out in the order in which they attained dominion status or independence; dates indicate either when colonies were first organized or claimed, or when relevant treaties were signed.)

1960 census, unless otherwise indicated. † 1961 census. ‡ 1963 census. § Winter 1965, fluctuates according to season. || Estimate. ¶ 1962 census. ¶ 1965 estimate. 1966 count. □ Uninhabited. ° Excludes states under special treaty with the U.K.: Bahrain, Muscat and Oman, Qatar, Trucial States. ▲ 1966 estimate. + 1966 census. 1961/62 census, \*\* 1959 census.

since no such demonstration was necessary, the Commonwealth association has proved sufficiently flexible to contain discordant elements, while continuing, in quieter ways, to foster the more humdrum nonpolitical links.

3. **Remaining Dependencies.**—In spite of the large number of countries that achieved independence after World War II, several dependencies remained under British and Australian control. In some cases independence was delayed because of local factors; in others it was affected by international politics.

The most notable case was Rhodesia, known as Southern Rhodesia before the dissolution in 1963 of the Federation of Rhodesia and Nyasaland, of which it was a part. The other two parts of the federation, Northern Rhodesia and Nyasaland, became independent Commonwealth members as Zambia and Malawi. Although there had been internal self-government in Rhodesia since 1923, its claim to independence was denied by Britain because the African majority was under the effective control of a small minority of European descent. The British government's refusal to grant in-

dependence under existing conditions was endorsed by other Commonwealth member states. In November 1965 the Rhodesian government took the extreme course of a unilateral declaration of independence. Although its legality was not recognized in formal terms by any other nation, the regime managed to sustain itself. Thus, while Rhodesia was still a British dependency, its government proclaimed that it was an independent state.

By 1967 the only other British dependency in Africa was the protectorate of Swaziland. Swaziland was close to independence, but it was recognized that its continued existence as a sovereign state would be dependent on the favour of South Africa, with which its economy was intertwined and within which it was a landlocked enclave.

In the Indian Ocean the island of Mauritius constituted the main British responsibility. It had internal self-government, but independence had been delayed by strains within its racially mixed population and by some concern about whether it could shoulder the economic burdens of full autonomy.

In the Middle East, an area of unusual turbulence in British colonial affairs, the Federation of South Arabia was the only remaining candidate for independence. Composed of disparate elements in the sheikhdoms of the interior and the cosmopolitan port of Aden, this federation was under constant fire from neighbouring Arab states, especially the United Arab Republic; its future also depended on the extent of British military assistance, which seemed likely to diminish following the British decision of 1966 to withdraw by stages from Aden as a military base.

In Asia only Hong Kong remained as an important British dependency, small in physical size but the largest of all in population. Hong Kong's people are Chinese; the colony is an historical anachronism which the Communist Chinese government could subdue without much difficulty if it chose. Part of the colony (the New Territories) was on lease from China.

Britain retained 11 territories in the Caribbean, of which British Honduras was the most contentious. There were schemes for federal union among some of the islands, but they faced, in an extreme form, the problems of poverty, remoteness, and nonviability which plagued the former Federation of the West Indies. British Honduras, on the Central American mainland, was involved in a long dispute between Britain and Guatemala, with which British Honduras has much in common.

In the Pacific Ocean Fiji was the principal British dependency. The movement toward self-government was slow because of disparities between the indigenous Fijian and immigrant Asian Indian communities. In this area the one important Australian dependency, the territory of Papua and New Guinea, provided a problem of self-government for the future. The backwardness of the great majority of the population and also the primitive character of the economy necessitated heavy financial assistance from Australia. The closeness of the territory to Australia itself created strategic problems. The Australian government said that the New Guineans would decide their own future status.

It was reasonable to expect that all these territories would move toward greater self-government, but unreasonable to assume that they would all become independent Commonwealth members. In South Arabia and Hong Kong external political circumstances would probably inhibit any wish to join the Commonwealth. Rhodesia could hardly become a Commonwealth member under its white-dominated regime, in view of the hostility toward that regime of African and Asian Commonwealth members. New Guinea's contacts were exclusively with Australia, and included few of those connections with Britain which, in all past cases, had been the important element in a decision to apply for Commonwealth membership. Fiji, Mauritius, and any Caribbean state, on the other hand, might be expected to seek membership.

**4. Lines of Change.**—Since the Commonwealth is essentially flexible and informal, its capacity for adaptation is considerable. It has managed to survive numerous changes. Being consultative rather than executive, and respecting differences between its members as a necessary part of its operations, it can survive considerable change in the composition and political interests of its members so long as they retain the wish to keep it in operation. However, it was often suggested that certain trends of the 1960s were likely to present stiff challenges to the Commonwealth.

Foremost among these was the possibility that Britain might enter a European political union. Such a possibility, if it occurred, would radically change the status of Britain, since its effect would be to withdraw Britain from independent diplomacy. In such circumstances there would be little point in other sovereign states trying to continue an association which had previously rested upon Britain's prominence as a major power. A Britain unable to provide special opportunities in trade, investment, defense, and diplomacy would be of little compelling interest to other Commonwealth members. Short of a European federal union, however, Britain could still provide some advantages.

Meanwhile, trade within the Commonwealth was declining in the 1960s as a proportion of the total trade of Commonwealth members. European countries such as West Germany, together with Japan, the United States, and Communist China, exerted considerable attraction. It was likely that this decline would continue,

making less significant any general concessions which Britain might give to other members of the Commonwealth. Similarly, an increase in investment capital from the other major industrial powers would make Britain less important to its partners and would give the sterling area less significance than it enjoyed when Britain was their main or sole source of capital.

It was noticeable that the U.S. played an ever larger part in the lives of certain Commonwealth countries, such as Canada, Australia, and New Zealand, and that U.S. aid was a substantial factor in the economies of others, such as India and Pakistan. Increased dependence upon the United States put Britain in a similar position. United States policy was not, however, hostile toward the Commonwealth, and it was unlikely that U.S. influence would be used deliberately to diminish its importance to its members.

There were also regional pressures which caused some members to turn away from emphasis upon the Commonwealth, especially in Asia and Africa, and in Europe so far as Britain was concerned. However, the Commonwealth provided a worldwide association which enabled its members to maintain contacts outside their immediate surroundings. In this its utility was matched only by the United Nations. Since it imposed no obligations, its members would probably wish to keep it as an extra diplomatic resource even if its immediate advantages in trade and finance should be reduced.

(J. D. B. M.)

## II. THE BRITISH EMPIRE

If the history of the British Empire during the three centuries before 1914 is considered primarily in relation to its subsequent transformation into the Commonwealth of Nations, the emphasis must throughout be placed on its political and constitutional characteristics. From 1914 until about 1945 first the Empire and then the Commonwealth was divided into two disparate segments. On the one side stood the dominions which, in 1914, already possessed full internal self-government and later became sovereign states; and on the other were the British dependencies chiefly in Africa, Asia, the Caribbean, and the Pacific which, for the most part, were ruled autocratically by the imperial power. In 1914 there seemed no bridge between the two groups. It was only in 1917, at the earliest, that India and Ceylon began to be seen as possible aspirants to equality of status with the dominions, and only in 1947, when India and Pakistan became independent, that the foundations were laid for a new multiracial Commonwealth in which almost all onetime dependencies might become sovereign and equal.

These fundamental contrasts between self-governing and subordinate British possessions were the product of two conflicting traditions of empire building. One was colonization by British settlers who, from the start, were assumed to take with them the right to substantial political freedom. The other was domination over non-British societies by the application of superior power. The history of these traditions is confused by the fact that some dependencies had moved from one to the other before 1914; but the central theme of British imperial history on its constitutional side is the parallel growth of these principles of colonization and domination and their eventual fusion in the Commonwealth.

### A. THE EMPIRE BEFORE 1763

There are no satisfactory boundary lines in British imperial history, but 1763, the date of the end of the Seven Years' War, is a convenient point at which to divide the first English experiment in overseas colonization from later developments. During this first period the principle of colonial self-government was firmly established, not only in North America and the Caribbean but also, transiently, in the few British possessions in Africa and the Far East which, because they were established and run by chartered companies, were never under direct imperial control. It is important to consider why the English, alone among European powers, permitted their colonies such autonomy from the start.

**1. The Constitutional Roots of the Early English Empire.**—The history of the English Empire (as indeed of all early European empires) began at home. There was no break in time or principle between attitudes toward dependent territories within Europe and those established overseas. The English tradition grew con-

tinuously from the 11th century and possibly earlier. In 1066 England in fact became a colony of Normandy, and later, by an interesting inversion of roles (which might have been repeated later if the English colonies in North America had not become independent) the colony became the metropolis and the centre of a considerable empire within Europe. As dukes of Normandy and then, by marriage, counts of Anjou and dukes of Aquitaine, the kings of England inherited a multiplicity of "dominions" outside the "realm" of England; and to these they later added Ireland, Wales, and the Isle of Man. Although all the continental possessions were lost by the late 16th century, traditions and usages deriving from this empire passed into English colonization in the modern period. Four of these were of particular importance.

First, the monarchy was unitary. Although the dominions were distinct from the realm of England, none was a kingdom in its own right; they were possessions of the crown of England. Secondly, the dominions possessed their own laws and customs, except in so far as common laws and regulations were imposed on them or were adopted by them. Thirdly, the dominions possessed their own legislatures, which were competent and indeed expected to undertake the bulk of legislation for themselves, subject to the royal right to initiate or veto their enactments. Finally, however, the king had broad powers to legislate for any dominion, either by virtue of his prerogative, or by acts passed by the English Parliament. Thus, the king in council could issue orders binding the dominions and hear appeals from their courts of law. Equally, although the dominions were not represented in it, an act of the English Parliament bound them, provided the act specified that it applied to one or more of them. In practice few English acts affected them. However, some did, and these nullified in advance the claim made later in America and Ireland that dominion legislatures had an exclusive right to make laws for their own territories.

Thus, before any Englishman set foot in America, England possessed an empire in microcosm from which the later overseas empire grew naturally. However, the character of American colonies also owed much to more immediate factors: in particular to the chronology of English colonization and to the agencies which undertook early exploration, trade, and settlement.

**2. English Colonization in America to 1688.**—England joined the ranks of the European empire-builders in America relatively late. Within a decade of the discovery by Columbus in 1492 of the Caribbean islands, Spain had established the nucleus of a territorial empire in America, claiming a monopoly of the whole continent by virtue of papal bulls and the Treaty of Tordesillas made with Portugal in 1494. The first permanent English colony in America, Virginia, was not established until 1607. There were several reasons for this delay. England was a small and relatively poor country, without the technical experience and skills to be found in southern Europe. Its people lacked the crusading spirit and missionary zeal which were so prominent in the activities of the Spanish and Portuguese overseas, and its monarchs were mostly unwilling and unable to invest large sums in overseas expeditions. Hence, for a century after 1494 the English did little more than prey on the colonies of other powers and on their trade.

The consequences for the future pattern of English colonization of this period of irresponsible interloping were, however, important. By the later 16th century only the Atlantic coast of North America and some of the Caribbean islands were still open for colonization. These had either been ignored or evacuated after investigation by Spain, mainly because none of them offered either bullion or the right climatic and demographic conditions: that is, they were unsuited for founding "mixed" colonies in which American Indians acted as a labour force in mines or landed estates. For the same reasons it eventually proved impossible for the English to duplicate the wealthy Spanish colonies in Mexico or Peru. They were left with two options: either to create plantations on the Brazilian model, importing African slaves as a labour force to grow sugar and tobacco, or to establish colonies of settlement which might be merely self-sufficient refuges for emigrants and of little use to the mother country. In fact they did both; and to this extent the economic and social character of the English empire in America was dictated by geography and chronology.

A second factor influencing the pattern of English colonization in its political aspect was the type of agency adopted for making settlements. The crown was unable to take the initiative for lack of resources, and every English colony was established by private agencies under royal license. Two alternative devices were adopted by the crown in authorizing such activities. First, it might grant a patent for the exploration or settlement of a particular area, such as the patent granted to John Cabot in 1496, which authorized him to search for new lands and granted him a monopoly of any trade he might establish there. The crown was to receive only one-fifth of any profits he made. Similar patents were widely issued during the following 150 years, though later they were normally granted to companies rather than to individuals, since the evolution of the joint-stock company provided a convenient means of raising money for risky overseas ventures. No distinction was made between companies for trade, piracy, or colonization. Thus the Muscovy Company was given a royal charter to establish a monopolistic trade with Archangel in 1555, and was followed by many others, including the East India Company in 1600, the Virginia Company in 1606, and the Massachusetts Bay Company in 1629. Such companies were expected to maintain their headquarters in England, under royal supervision, but they were given almost complete freedom of action, including government, within their allotted areas; and some companies eventually transferred themselves entirely to the colonies they had established in America. Such chartered rights, transmuted into colonial governments, reinforced the liberties normally possessed by dominions of the crown under direct royal control.

The alternative means by which the crown authorized its subjects to establish colonies was to grant a particular territory to an individual or group in the form of a medieval fief, with or without knight service. Durham and the Isle of Man survived as palatinates of this kind, and the device was being used in Ireland. It was readily adapted to America, though it was not thought suitable for use in Africa and the East, where territorial domains were not contemplated. Thus, whereas Virginia, Bermuda, and Plymouth, Mass., were established by chartered companies, the bulk of the other continental and Caribbean colonies were originally granted in fief to individuals or groups.

The period of company or proprietary rule was, however, brief in most colonies. Financial failure, wars, technical breaches of the terms of the grant, and eventually English anxiety to bring the colonies under closer control led to most charters or grants being cancelled. Virginia, which lost its charter in 1624, became the first "royal" colony in America, falling into line with Ireland and the Channel Islands as a conventional dominion of the crown with royal governors and officials. In the 18th century the only surviving chartered colonies were Massachusetts, Connecticut, and Rhode Island, each of which had lost its charter between 1684 and 1688, but had regained one in 1691. Pennsylvania and Maryland were the only remaining proprietary colonies. Yet the initial period of chartered or proprietary rule had important long-term consequences for the character of the American colonies. It had created a tradition that the crown would not interfere directly in their internal affairs and thus strengthened the existing tradition of autonomy in the royal dominions. Even the end of the charters and grants and conversion into "royal" colonies did not convince the colonists that their rights could be abridged by the crown.

These constitutional traditions making for colonial autonomy were strengthened by the character and attitudes of many individual colonists. For the most part men emigrated to North America because they hoped for greater prosperity there than at home. In the early 17th century English emigration was stimulated by rising land rents, engrossment of farms, unemployment in the textile industry, and widespread poverty. In later years similar economic problems in Ireland, Scotland, and Germany generated additional emigration to the British colonies, giving them an unusually polyglot character. In addition, there were many indentured servants and transported convicts who became free settlers after a period of servitude. All naturally assumed that in the new world they would escape from the restrictions of the old and to that extent expected freedom to run their own

affairs. But in New England the desire for autonomy was heightened by the fact that several early colonizing groups, particularly the Massachusetts Bay Company settlers, were dominated by Puritans, who resented the intolerance of the Anglican Church at home and went to America with the express purpose of setting up theocratic republics, recognizing only the most distant loyalty to England. Taking the self-regulating nonconformist congregation as their political model, the Massachusetts Puritans and the smaller groups which later founded settlements in Connecticut and Rhode Island, made their own laws and institutions in the light of scripture and common sense. From the start such colonies resented English interference and attempted to evade all controls. Although not in most respects typical of the colonies to the south, this New England tradition ultimately became a dominant influence in the movement toward independence after 1763.

**3. The Old Colonial System, 1689-1763.**—By the 1690s the American colonies had weathered various attempts—in the 1630s, the 1650s, and the 1680s—to reverse these early traditions, and were settling into what may be called the classical period of the old Empire. It was to these years that the colonists were to look back after 1763 as to a golden age, when they were left very largely to their own devices and their rights were regarded as sacrosanct. On the political side such rosy memories were justified. In practice at least, the American colonies were free to an extent equaled only by settlement colonies with responsible government during the 19th century. Moreover, legal and chartered rights were strengthened by the inadequacy of most royal agencies designed to exercise the crown's authority over them. Within the colonies royal governors were hamstrung by their dependence on assemblies for revenue and sometimes even for their own salaries. Subordinate officials appointed from England were few and generally nonresident. In England there was no single agency with exclusive responsibility for supervising the colonies. There was an American Department between 1768 and 1782, but no department dealing specifically with the colonies existed until 1801. Colonial questions were therefore dealt with variously by the secretary of state for the Southern Department, who handled correspondence; by the Privy Council or one of its committees, which advised the crown; by the Board of Trade and Plantations (1696 to 1782), which was solely an advisory body; and by any British department the responsibilities of which extended to the colonies: the Treasury, Customs Commissioners, Post Office, Admiralty, War Office, and even the bishop of London. Such dispersal of authority meant that colonists were often bothered but never oppressed.

Parliament, of course, had an undoubted right to legislate on colonial matters, even though colonists were not represented in it. Yet, before the 1760s, Parliament was seldom concerned with the colonies. No colonial constitution originated in Parliament before 1765. No taxes were imposed on the colonies by Parliament, excluding dubious cases such as the legislation under the Post Office Act of 1710. Most British acts, such as the penal laws, did not extend to colonies. The one sphere in which Parliament frequently legislated on colonial questions was that of trade and production. The navigation acts and other statutes regulating colonial economic life constituted the main "imperial factor" in the early British Empire.

Economic legislation fell into two categories. First there was a series of acts which started with one passed by the Commonwealth Parliament in 1650 and continued in 1651, 1660, 1662, 1663, 1671, 1673, and 1696. These came to be regarded collectively as the navigation laws and the fundamental commercial code of the empire. Their effect was to insist that all trade to or from the colonies should be carried in British ships (which included those built in the colonies); that, with a few exceptions, all goods going to the colonies, whatever their place of origin, should pass through a British port; and that any colonial export staple which Britain chose to enumerate should go directly to a British port, whatever its ultimate destination. The aim of these laws was to ensure a monopoly of all colonial trade and its transport. This was done partly to exclude foreign competition and so increase British profit margins, and partly to provide an arti-

ficial basis for a large merchant marine as a reserve of ships and seamen for use by the Royal Navy in time of war. Parallel with these acts were others which put restrictions on any colonial manufacture or process which appeared likely to compete with a British interest. The 1699 Wool Act forbade the export of wool, yarn, or cloth from any colony; the 1732 Hat Act imposed a similar restriction and also required English apprenticeship regulations; and the 1750 Iron Act banned new slitting or rolling mills in the colonies, while encouraging production and export to Britain of pig iron. Yet there was no rationality in such restrictions. They were imposed where vested interests in Britain succeeded in convincing Parliament of their case. In this British shipbuilders failed, and colonial shipbuilding was strongly encouraged.

Thus the general situation of the American colonies in the century or so before they achieved independence was a paradox which Edmund Burke accurately defined as a "state of commercial servitude and civil liberty." The colonies were largely autonomous dominions of the crown, but were strictly controlled in the economic sphere. In each case, however, they were more free in practice than in theory. The constitutional rights of the crown were eroded by the ingenious use made by assemblies of the power of the purse. The commercial regulations were evaded where most inconvenient by smuggling. It can, in fact, be said that the "golden age" depended on a largely fortuitous balance between theory and practice, between British authority and colonial rights. The most probable source of trouble was disturbance of this balance by either party.

**4. The British in Africa and the East Before 1763.**—During the century and a half before 1763, while the empire in America grew into a substantial territorial block, the English established no comparable empire in Africa or the East. This was not surprising, for in these regions England followed models created by Portugal and Holland, both of which countries took it as their first principle that there was no advantage in establishing territorial empires outside the Atlantic area. Their reasons were compelling. Territorial occupation was necessary in America because the western hemisphere did not otherwise provide adequate commodities for profitable trade. Only effective occupation and settlement could exploit bullion resources and valuable primary products. Conversely, in the established trading zones of Africa and the East, commodities were already available for trade (gold, ivory, ebony, and slaves from West Africa and parts of East Africa; spices, local manufactures, and a wide range of luxuries from the East), and indigenous commercial organizations existed to provide them. Large colonies were not, therefore, necessary for trade, though small bases were desirable for security and to provide food and repair facilities for European ships. Moreover, there was no probability of European emigration on a large scale to Africa or the East, and for long it would have been militarily difficult, if not impossible, to conquer the more powerful kingdoms Europeans discovered in these regions.

Until about 1757, therefore, the English treated Africa and the East in much the same way as the more remote and difficult trading areas of Europe and the Levant, as places in which it was desirable to establish commerce with a minimum of political involvement. The obvious instrument was the chartered company, which, on the lines of the regulated Merchant Adventurers Company, could be given a commercial monopoly of a particular area together with wide powers to run its own affairs and come to terms with non-European states.

England had no interest in eastern or southern Africa; but from 1588 the crown made a series of grants to groups or companies giving them a monopoly of part or all of the West African coast. In 1672 rights over the whole of West Africa were given to the Royal African Company, a joint-stock body, which inherited and consolidated forts on the Gambia River and on the Gold Coast. This company survived until 1750, when it gladly gave up its charter and monopoly. It had, in the end, been defeated by the high cost of maintaining its forts against Africans and rival Europeans, especially in time of war in Europe. Moreover, after 1698 it had been forced to allow private English traders to use its forts on payment of duties, thus losing its monopoly of the slave trade

with the Caribbean. After its dissolution the company's forts were handed over to a regulated corporation, the Company of Merchants Trading to Africa, which ran them, with the help of government subsidies, until 1821. Meantime, the only substantial increase of British territory or influence consisted in the possession of French Senegal (from 1763 to 1783) and in the new colony of Sierra Leone, set up by a group of humanitarians in 1787 and reestablished in 1791, primarily to provide a refuge for the many West Indian slaves who were released in England as a consequence of Lord Mansfield's judgment of 1772 that slavery was unknown to the law of England. Although in the 19th century substantial British colonies were to grow from these few roots, as late as 1815 they did not constitute a territorial empire.

In India and farther east much the same was true until 1757 (the Battle of Plassey). In 1600 the crown granted a charter and a monopoly of trade east of the Cape of Good Hope to the English East India Company, which proceeded to establish trading bases in India and the East Indies. This company had a more or less continuous existence thereafter, though at various times before 1657 the crown granted charters to rival companies, and in 1701 the company nominally lost its monopoly to a rival "New Company," which had outbid it for the monopoly. In fact, however, the two groups agreed to join forces and were fused in 1709 as the United Company.

At this time the company still possessed very little territory. It had failed to break into the Dutch monopoly of the Indonesian Archipelago and kept only a derelict base at Bengkulu in western Sumatra. In India it had three substantial fortified trading bases, at Bombay, Madras, and Calcutta, the first held in sovereignty after being ceded to the crown by Portugal in 1661, and the others only on leases granted by the Mughal emperors. In addition there were a number of warehouses in some of the more profitable trading centres. The company, in fact, remained a conservative trading concern, providing its shareholders with modest dividends (7% or 8% for much of the 18th century), and was a source of loans to the British Treasury. So long as it did not expand its possessions or become bankrupt it was safe from governmental interference. The critical period began in the 1740s. Wars with France for control of the Carnatic, a region on the east coast of India, and the steady drift toward political anarchy in India as the Mughal Empire decayed forced the company to spend more on military efforts and to involve itself in Indian politics. The Seven Years' War left it political master of the Carnatic, the French retaining only unfortified trading posts. More important, a surprise attack by the nawab of Bengal on Calcutta in 1756 led to British counterattack in 1757 under Robert Clive (*q.v.*), and to the unexpectedly complete victory at Plassey. By 1764 this victory had been consolidated and the company was not only master of Bengal but the dominant power in Hindustan.

Thus, at the moment when the settlement empire in America was approaching its period of crisis, the British were almost inadvertently laying the foundations of a still larger empire in the East. This fortuitous coincidence makes the 1760s the first main watershed in British imperial history, separating the era when the American colonies were the main component of the empire from the later period when its centre lay east of the Cape of Good Hope and most colonies were inhabited by non-Europeans.

#### B. THE CRISIS OF THE EMPIRE, 1763-1815

In the half century after 1763 there were two opposing tendencies at work. The British lost the bulk of their possessions in continental North America, but thereafter acquired many new colonies of widely differing types. The British Empire in the 19th century was the product of these disparate trends.

1. **The Revolt of the American Colonies.**—In retrospect it seems probable that the British colonies of the North American continent were bound eventually to demand independence, for in course of time they were growing away from the parent state, and it was always possible that the balance of interests which had made the imperial system acceptable to them might be disturbed. Yet it is important not to believe that revolution had for long been incipient. The crisis grew quickly from changed circumstances

in North America during the 20 years before 1763 and not from profound resentment at British exploitation.

The wars of the period 1739-63 disproved two assumptions common in Britain and the colonies: first, that individual colonies could safely exist in isolation from each other and from Britain because they were sufficiently far from foreign enemies so that a common political and military organization was unnecessary; and secondly, that Britain had no reason to interfere in the domestic affairs of the colonies. Because North America became a major theatre of war in the struggles between Britain and France the British were forced to undertake active operations there and to impose some degree of coordination on the military forces of the individual colonies. Evidence of colonial evasion of the wartime ban on trade with enemy states stimulated Britain to impose an efficient naval search for smugglers.

Above all, the victory over France and the cession to Britain in 1763 of Quebec and all French claims to land between the Appalachians and the Mississippi changed the whole North American position. With France out of the way the Middle West was potentially open to British settlement. On the other hand, the Indian tribes of this area, who had hitherto retained their independence by playing off the English against the French, were likely to resent large-scale settlement, which, in any case, was certain to destroy the much-valued fur trade of the region. For the first time, therefore, the British had to contrive a policy for these western lands, balancing the interests of settlers, land speculators, Indians, and fur traders; and this again meant direct imperial intervention, overriding the special interests of individual colonies. If intervention took the form of policing the western lands with a military force, the problem of finance would necessarily arise, and with it the question whether colonists should be made to contribute to imperial expenditure on their behalf. Thus, the general effect of the period 1739-63 was to raise new problems while it removed old dangers. Above all, the era of colonial isolation had ended and a period of British intervention had already begun.

In view of the British colonial tradition any intervention was liable to be resented. In the 1760s intervention fell into two broad categories. First, there were a number of administrative laws and actions which attempted to increase efficiency in various fields—customs collection, currency, arrangements for quartering the British army, the trial of cases arising from smuggling—and to regulate the western lands. Secondly, there were taxes imposed on various imports in 1764 and 1767 and the Stamp Duty in 1765. Although British actions in both categories annoyed many colonists, most of the controversy developed over taxation simply because most other British policies raised no obvious question of principle and rights and therefore were less easy to denounce. However, the debate over taxation raised fundamental issues. The fact that it was inconclusive, because few in Britain or America ever accepted the other side's point of view, was unimportant. By 1770 most Americans were thoroughly suspicious of Britain, and their sense of having a distinct identity had been stimulated to the point at which it can usefully be described as nationalism.

Yet it is wrong to assume that revolution was inevitable by 1770. By then Britain had withdrawn most of the taxes and had softened other policies to the point at which they became tolerable to most colonists. During the next three years it appeared that most in America wanted only an end to controversy and a return to the golden age. One view of the revolution is that it was largely the product of deliberate agitation by an active radical minority who had emerged as the leaders of the nationalist movement in the 1760s and who, whether for "patriotic" motives or because they feared a return to earlier conditions would end their moment of power and importance, were determined to force Britain into further inflammatory actions. By means of such partly contrived events as the Boston "massacre" of 1770, the Gaspée affair in 1772, and finally the Boston Tea Party late in 1773 they fed the myth that the British were tyrannical and kept the nationalist movement in being. Their success came when the British attempted to punish Massachusetts for the Tea Party by passing the Intolerable Acts of 1774, which closed the Boston harbour until it displayed proper respect for British authority and aimed

at making Massachusetts into a standard royal province. These measures aroused general colonial hostility and support for Massachusetts. The radicals used the Continental Congress of 1774 to lead the national movement and to demand terms which the British could not accept. The result was a steady drift to informal fighting in New England; and in 1776 the Continental Congress accepted the view that if the war was to be fought successfully it must have the specific aim of achieving full independence. Largely as a result of French, Spanish, and Dutch intervention on the side of the Americans Britain had lost the war by 1782, and in 1783 the United States was recognized as a sovereign state. For an extended discussion and other interpretations of this conflict, see UNITED STATES (OF AMERICA): *History: The Contest for Independence 1763-1783; AMERICAN REVOLUTION*.

**2. The Acquisition of New Possessions, 1763-1815.**—The loss of the United States appeared to many to mark the virtual end of the British Empire. Yet, by 1815, Britain was once again a great imperial power possessing territories in many parts of the world from which a still greater empire was to grow.

The character of this reconstituted empire was, however, substantially different. Although it still contained colonies in the Americas—Canada, Nova Scotia, New Brunswick, Newfoundland, Hudson Bay, the older Caribbean Islands, and new islands such as Trinidad, Tobago, and St. Lucia—its centre of gravity now lay elsewhere. The acquisition of the Cape of Good Hope in 1795 led inexorably to British predominance in southern Africa. The annexation of Ceylon, Mauritius, the Seychelles, the Maldives, and Penang between 1786 and 1815, followed by Singapore in 1819 and Malacca in 1824, made the Indian Ocean a British preserve. Continued rapid expansion within India made the East India Company the dominant power in the subcontinent by 1818. Even in the Pacific there was a colony in New South Wales, and British influence was spreading through the islands of the South Pacific.

Several novel features of this early 19th century Empire stand out. First, only the relatively few surviving American colonies were in the older tradition of European settlement societies. The others were intended to serve quite different British interests or were chance acquisitions without obvious utility. Thus the Cape, Ceylon, Penang, Singapore, Malacca, and the islands in the Indian Ocean were all annexed to safeguard the sea routes to India or China, or to act as trading entrepôts between India and China. The British did not want them for their own sake—that is, to settle there or to establish plantations—but because the new hostility of Holland after 1780, followed by the occupation of that country by France in the 1790s, made it seem necessary to annex strategic Dutch bases which were vital to British power in India and the East. Similarly, Mauritius was taken from France to make it impossible for the French to maintain a naval force in the Indian Ocean. Expansion in India was the outcome of complex forces: constant friction with the "country powers" (independent Indian states), fear of French intervention, company greed for further land revenue to add to that from Bengal, and the growth of anarchy following the decay of Mughal power. Finally New South Wales in Australia, far from being the outcome of renewed enthusiasm for settlement colonies on the American pattern, was established primarily as a distant prison for British criminals once the American colonies could no longer be used for that purpose. Thus, the "new" empire lacked any common root or function, and its diversity reflected the multiplicity of new forces which were to be characteristic of imperial expansion during the 19th century.

A second and consequential feature of this empire was the variety of constitutional forms and racial groups it comprised. The earlier empire had been united in language, law, and basically similar systems of government, all deriving from the parent state. By 1815 the colonies were almost as diverse as they were numerous. Some, including the one-time French, Dutch, and Spanish territories, had European languages, laws, and institutions, yet were alien to the British tradition. By contrast with similar colonies obtained in 1763 (Canada, Grenada, and Florida) French, Spanish, and Dutch possessions occupied during the wars between

1793 and 1815 were not granted representative constitutions. English laws but were administered by autocratic governors along broadly the same lines as before conquest. Until 1815 such autocracy and conservatism were seen merely as convenient during a temporary military occupation. Thereafter they became gradually accepted as permanent because convenient; and by the 1830s the system was sufficiently regularized to be labeled "crown colony government." In course of time English language, laws, and some administrative institutions were superimposed on those inherited from the past; but the basic formula of nonrepresentative government, an autocratic governor, an advisory executive council, and, in most cases, a nominated legislative council, survived as the common feature of most British colonies other than those with "responsible government" (see below) from 1815 to 1914.

Such institutions were, however, fully adapted only to one-time European colonies, which had been conquered by or ceded to Britain. They could be used, with modification, in places like New South Wales, Sierra Leone, Ceylon, or the Gambia. They were, however, not necessarily applicable to an area as vast as India or to other colonies with no tradition of European government. In India the problem of size, numbers, diversity of religions and laws, the absence of any large number of European settlers, distance from Britain, and the existence of a chartered company as intermediary between the crown and British possessions posed unique problems.

Basically, two main questions faced the British government and the East India Company from the moment of the conquest of Bengal in the 1760s. Should the company be allowed to administer such vast areas or should the crown take direct responsibility? What forms of government within India would be best adapted to widely contrasting conditions in different areas: for example, should the British undertake direct administration and build up a corps of professional administrators, or should they act through Indian agents and use indigenous forms?

By 1815 answers had been found by trial and error which survived virtually unchanged until the end of company rule in 1858. From the passage of Pitt's India Act in 1784, the company retained its commercial rights and controlled all government and policy within India; but a body of royal commissioners, the Board of Control, had power to see and amend all dispatches sent by the company to India and could send its own orders to the governor-general through a secret committee of the company. Such dual control was in some ways inefficient, but it worked surprisingly well. In India also compromises were made. A large part of the country was left in the hands of Indian princes, some of whom were bound by formal treaty, others by informal arrangements to accept British advisers and to pay tribute. This was "indirect rule." Conversely, British India—those regions taken into possession by the company—was directly administered by expatriate company officials, though there also Indian laws and administrative methods were very largely preserved.

Thus, by 1815, a basic split already existed within the surviving British Empire. In one camp stood the relatively few colonies of British settlement in America and the Caribbean which retained the traditional system of representative government and had English laws and institutions. These included the slave islands in the Caribbean and also Quebec which, after 1791, had been given a new variant of the old representative system of government. In the other camp were the multiplicity of new possessions, which because they were at one time foreign colonies, or because they were obviously not adapted to European forms of government, were not assimilated to the older model. During the following century the contrast between the two groups widened as the settlement colonies achieved responsible government and many more tropical colonies were acquired.

**3. Mercantilism.**—However, in 1815 one major feature of the older imperial system—mercantilism—survived virtually unchanged. The navigation laws (*q.v.*) were threatened in the 17th century both by theoretical attacks made on them by men like Adam Smith and by the exclusion of the United States from their scope. There seemed a real chance in 1782-83 that Britain might begin to throw some of its colonies open to foreign ships. In fact,

did not do so. Conservative opinion rallied. The U.S. was excluded from the imperial shipping monopoly, even in the West Indies. A few "free ports" were opened in the Caribbean and later in North America, but these were virtually the only concession made to freedom of trade. At the same time it proved impossible and undesirable fully to impose the navigation acts east of the Cape. Foreigners were allowed to trade with British possessions in the Indian Ocean and in the Pacific, provided always that they did not take goods directly to or from Britain, since this would have been inconsistent with the East India Company's monopoly. Only after 1820 was this degree of economic liberalism applied also to British possessions in the Atlantic.

### C. THE BRITISH EMPIRE IN THE LIBERAL ERA, 1815-1880

The period after 1815 has often been labeled one of "anti-imperialism." This is misleading. The British did not fundamentally turn against empire, and they did not give up any of their possessions other than the protected Ionian Islands (1864). On the contrary British dependencies increased in number and size at a remarkable speed. In India the area directly controlled by the East India Company was steadily increased by incorporating a number of princely states and by annexing border areas such as the Punjab, Sind, and parts of Burma. By 1880 Britain had acquired protectorate treaties over three Malay States; it took Hong Kong as an entrepôt station in 1842, New Zealand in 1840, and Fiji in 1874. In West Africa existing settlements had expanded along the coast and Lagos had been annexed. In southern Africa the borders of the Cape had been pushed far to the east, and inland settlements had been established in the Transvaal and the Orange Free State. Meantime, most of Australia had been surveyed and new colonies founded in Queensland, Victoria, South Australia, and Western Australia. In North America British territories stretched from the Atlantic to the Pacific.

The element of truth in the legend of "anti-imperialism" is that very few of these new acquisitions were the product of demand in Britain. Most were the result of local expansionist forces over which Britain had little control and which it often attempted to check. Under changed conditions after 1815, when most rival colonial empires were disintegrating, there seemed no positive advantage in extending British possessions. Conversely, experience suggested that every new colony entailed inconvenience and expense. Hence, only an unanswerable case for expansion seemed to justify annexation; most actual acquisitions did not seem to be justified in this sense but nevertheless seemed irreversible.

Movements of British settlers in South Africa, Australia, New Zealand, and North America from initial small areas were impossible to contain. The unsettled condition of India after 1815 and the considerable freedom of action possessed by the East India Company until its powers and possessions passed to the crown in 1858 made expansion into regions of instability around the company's existing possessions almost inevitable. Elsewhere, the freedom of contacts between British traders, missionaries, and colonial authorities, and neighbouring indigenous peoples, particularly in West Africa and the Pacific, led to situations in which annexations were unavoidable. In short, the characteristic British attitude to empire in this period was one of cautious cynicism as to the possible advantages of new possessions, coupled with resigned acceptance of the inevitable once its inevitability had been demonstrated. This was not so much "anti-imperialism" as a measured assessment of the facts of each case as it arose, which in turn was possible largely because there was no foreign interference in most of the areas involved. The main change after 1815 was that international rivalry for colonies made such a measured assessment less feasible, so that Britain had often to buy territory which it did not want for fear that others would preempt it.

Before the 1880s, however, territorial expansion seemed relatively unimportant. British interest in the empire centred on three distinctive features of this period: humanitarian attitudes to relations with non-Europeans, the establishment of free trade in place of the restrictions of mercantilism, and the growth of responsible government in the colonies of white settlement.

1. **The Humanitarians.**—Until the later 18th century European attitudes to the many non-European peoples with whom they came into contact had tended to be pragmatic. Theoretically, all countries aimed to convert them to Christianity and to "improve" them. In practice they dealt with them as seemed convenient, without undue concern for their welfare. Strong civilized states in Asia were treated with respect; weaker American Indian and African tribes were dealt with brusquely. North American Indians were relentlessly driven from their hunting grounds to make way for settlers, and millions of West Africans were transported as slaves to America. From the later 18th century, however, moral doubts on these questions grew stronger in France, England, and North America, stimulated both by the idealism of the Enlightenment and by the evangelical and Nonconformist religious revivals. The American slave trade and slavery itself were the first and most obvious targets of the humanitarians. In 1807 the British, who throughout the 19th century were the leaders of the humanitarian movement, ended their own slave trade, and thereafter worked through diplomacy and naval blockade to stop trading in slaves by other countries. In 1833 a British act made slavery illegal throughout the empire, though it tempered the blow to the slave-colonies by imposing a six-year period of "apprenticeship" for all former field slaves and four years for others.

The end of slavery in British possessions left the humanitarian movement in full flood and in need of new objectives. It therefore turned its attention to other relationships between Europeans and indigenous peoples. Led by the Aborigine Protection Society, humanitarians attempted to protect non-Europeans from the worst consequences of contacts with Europeans: to prevent quasi-slave labour under cover of "free contract"; to safeguard their land from white settlers; and to check the sale of alcohol and guns. To a large extent they succeeded wherever British authority was firmly established; though of course, from the standpoint of the later 20th century, their objectives may seem too limited in that few of them conceived it possible that non-Europeans could ever aspire to full political equality with Europeans. However, these attitudes and their limitations generated the concept of imperial "trusteeship" which dominated "native policy" in the new tropical empires acquired during the post-1880 partition of Africa.

2. **Free Trade.**—Freedom of trade between British colonies and other countries, coupled with the end of preferential tariffs and other artificial stimulants or restrictions on trade, exerted a profound influence on the character of the 19th-century British Empire. The end of commercial restrictions came by stages between 1824 and 1849. By 1830 Britain had opened its colonial trade to all foreign nations and their colonies, provided these gave reciprocal advantages, but it retained the monopoly of the direct carriage of goods between colonies and Britain until the final repeal of the navigation acts in 1849. In 1813 the East India Company lost its trading monopoly in India and in 1833 its monopoly of British trade east of the Cape of Good Hope. From 1846, also, preferential tariffs on colonial goods entering Britain and on British goods entering the colonies, together with bounties on colonial products sold in Britain, were gradually ended. By the 1860s Britain neither gave nor received any artificial economic advantage within the empire, and had a policy of free trade until 1932.

The reasons for this shift to free trade owed less to the economic doctrines of Adam Smith and the later classical economists than to the changed facts of international commerce after the dissolution of most rival American empires and the advantages Britain possessed as a result of its rapid technological advance. However, the effect of free trade on the character of the empire was considerable. It greatly strengthened British reluctance to acquire new colonies since they now provided no special economic advantages. Conversely, the end of preferences and bounties had a serious effect on some colonies, particularly the West Indian sugar islands, which had produced for a protected market; and in general it made the imperial connection seem less valuable to the colonies. However, perhaps the most important effect was on British attitudes to the government of colonies. Imperial authority and control had been valued partly because they were necessary to enforce the laws of trade. Now strict control

seemed unnecessary unless Britain had other important interests at stake in a particular colony. This did not mean that the Colonial Office immediately relaxed its supervision, but it did open the way to a wider devolution of power to those colonies which seemed capable of governing themselves and in which Britain had no strong interests. Thus, while naval bases like Gibraltar or colonies with serious racial problems like the West Indies might still require close supervision, settlement colonies in North America and Australasia might not. The adoption of free trade thus cleared the way for the concession of responsible government in certain colonies.

**3. Responsible Government.**—Responsible government (the name commonly given to the British system of cabinet government when applied in the colonies) was perhaps the most surprising innovation of the period 1815–80. In the past English colonies in America had been distinguished from those of other nations by their representative assemblies and the extent of their autonomy. However, these representative assemblies had not, in theory at least, controlled colonial governments. Their function was to vote taxes and pass acts, not to control the executive, though in practice they had often contrived to do this by exploiting their power to tax. Moreover, as long as the king maintained an effective share in government in England, appointing his ministers largely at will and influencing their policies (as in some degree remained the case until at least the 1830s), it would have been inconceivable for a colonial governor to delegate his authority to a cabinet of colonists who in turn depended primarily on support by the colonial assembly for their tenure of ministerial office. Even when a form of cabinet government was recognized to be operating in England—that is, by the 1840s—there still remained the objection that a colonial governor was merely an agent of the British government and could not share his responsibility with colonial ministers who might give him mandatory advice inconsistent with any orders he might receive from England.

Responsible government was therefore a radically new departure in colonial history. The way was cleared for its adoption by the new circumstances of the white settler colonies after about 1830. Canada and the other North American colonies already possessed representative government. The early settlements in Australia had a strong claim to it once they ceased to be primarily convict stations. New Zealand also rapidly developed into a typical colony of British settlement with similar claims, but in each case such claims were only to a representative system.

Further advance was made conceivable by the gradual dismantling of the navigation laws, clarification of the theory and practice of cabinet government in England, and by propaganda emanating from a group of radicals in Britain known as the Colonial Reformers. The case for maximum devolution of authority to the colonists was, moreover, supported by those in Britain who demanded economy in public expenditure on the grounds that a self-governing colony would cost less to defend and administer than one under close imperial control. However, the particular form this devolution took owed much to Lord Durham, a radical Whig peer who was sent to Canada in 1838 to report on the causes of two minor uprisings which had taken place in Upper and Lower Canada. His *Report on the Affairs of British North America* (1839) became the manifesto of the advanced school on colonial affairs. In it he argued that Britain could avoid trouble of this kind only by adopting the principle that for the most part colonial affairs were of no concern to the metropolis and could safely be left to responsible ministers chosen from the colonists. Britain had only four substantive interests in the colonies: colonial constitutions, foreign relations, international trade, and the disposal of wastelands. These interests should be retained under British control; the rest could be transferred to the colonists.

Initially, these principles seemed too radical and were rejected in London. But after 1846 Lord Grey, as colonial secretary, gave the North American governors freedom to act on them if they chose, and in 1848 Nova Scotia and Canada were allowed to form cabinets. The way seemed open for the new system to be extended, but extension raised two important questions. Was cabinet government applicable to all colonies? Was Durham's

definition of necessarily "imperial" fields of government permanently valid?

To the first question no answer was immediately forthcoming, but over the next 20 years the principle gradually emerged that any colony which had a sufficient number of free settlers of European stock to run a government efficiently might qualify. The growing British enthusiasm for economy generated the obverse principle that all such colonies must accept ministerial responsibility for internal matters, even against their inclinations, in order to relieve Britain of expenditure on matters such as defense. Despite some humanitarian doubts, it was also held that the presence of a large number of non-Europeans in a colony did not necessarily disqualify it for responsible government, even though the white minority might act contrary to the interests of the non-Europeans. It was on these grounds that Cape Colony, Natal, New Zealand, and eventually Southern Rhodesia (in 1923) obtained responsible government. However, by no means every colony which had representative institutions and white settlers qualified for ministerial responsibility. During the 19th century no colony which had too few Europeans to run a competent representative government without extending the franchise to a non-European majority lacking in the qualifications thought necessary—education, property, stability—was given ministerial responsibility. Thus India, Ceylon, most of the one-time slave islands of the Caribbean, and all other tropical dependencies were excluded. In the 1920s Kenya, which might well have qualified as a "settler" colony by the standards of the 1850s, was refused both representative and ministerial government on the novel grounds that the interests of the African majority must remain "paramount."

The long-term consequence of these pragmatic distinctions was to divide the Empire into three classes of colonies in place of the two (representative and crown colony) which existed in 1830. Colonies with responsible government formed an imperial elite, consisting of the North American colonies, which were joined in the quasi-federal Dominion of Canada in 1867; the Australian colonies, which formed the Commonwealth of Australia in 1901; New Zealand; the Cape of Good Hope and Natal, which joined the onetime Afrikaner republics of the Transvaal and Orange River Colony to form the Union of South Africa in 1910; and finally Newfoundland. In 1907 all these were given the title "dominion" to distinguish them from other colonies. Meantime, the older colonies which possessed representative institutions and might have acquired responsible government were split into two groups. A few, including Barbados, the Bahamas, and Bermuda, were left as they were to form a small middle grade of colonies without cabinets or ministers. The remainder of these older colonies, including the most important of them, Jamaica, were downgraded to join the third category of British colonies, India and the crown colonies, all of which (though with differences in detail) were automatically ruled by governors and councils. Thus, responsible government accentuated that division in the constitutional structure of the empire which began with the annexation of conquered colonies and other tropical dependencies in the later 18th century.

The second broad question posed by the application of Lord Durham's principles to certain colonies was whether his arbitrary distinction between "colonial" and "imperial" spheres of policy could be preserved, together with the fundamental doctrines of British parliamentary sovereignty and full control by the crown over colonial governors. Had these principles stood indefinitely they would have made it impossible for the self-governing colonies to evolve into quasi-sovereign states. In fact the British quickly recognized that to stand on these powers as a whole might force colonies eventually to claim independence: they preferred to concede one point after another, defending the principle rather than the substance of metropolitan authority.

By 1914 only one of Durham's "imperial" subjects had escaped colonial control. Wastelands were transferred to colonial governments in the 1850s, or when they acquired responsible ministries. Commercial and tariff policy was conceded after 1859 and by 1914 most dominions had protective tariffs and could choose to exclude themselves from international commercial treaties made by Britain. Constitutional amendments could be made by most

colonies under the terms of their constitutions, subject to approval by the crown. The 1867 British North America Act tacitly reserved amendment of the Canadian federal constitution for the British Parliament, but the 1900 Commonwealth of Australia Act and the 1909 Union of South Africa Act could both be amended by those dominions provided complex procedures were followed. Thus, only foreign relations remained entirely beyond the control of dominion governments, on the principle, still considered fundamental in 1914, that the Empire must remain a diplomatic entity and that the crown was responsible to foreign nations for acts of the dominions. In addition, the British Parliament retained its power (rarely used) to legislate for those dominions, and the crown possessed full control over governors.

Thus in 1914 the future of responsible government was still in doubt. Its meaning had changed substantially since 1848. The dominions were in most respects more like independent states than mere dependencies; yet there remained substantial legal and conventional barriers to full sovereign status. One of the main problems of imperial policy after 1914 was to determine how much further dominion independence should go. In the end it proved impossible to stop its progress, and in 1931 the Statute of Westminster virtually conceded full sovereignty to those dominions which chose to adopt it. Until 1949, when India became a republic, this was the basis of the Commonwealth as an association of sovereign states united in allegiance to the crown.

#### D. THE BRITISH EMPIRE, 1880-1914

Between 1880 and 1914 British imperial history was dominated by two major problems which remained almost entirely distinct. First, and the more important to most in Britain, was the future relationship between Britain and the self-governing settlement colonies. Second was the very rapid expansion of British dependencies in Africa and the East, the annexation of which raised major issues of policy which generated still more difficult administrative questions thereafter.

**1. Imperial Federation.**—The first issue derived from the constitutional evolution of the colonies with responsible government. By the 1870s it seemed to many that such colonies must eventually become sovereign states outside the Empire. Some welcomed this prospect, but others did not. To the latter it seemed vitally important that Britain should not lose contact with its offspring, partly because there were sentimental links of kinship and culture and partly because they came to believe that the long-term future of Britain, as a small island in a world of growing continental powers, might depend on close political and economic cooperation with its white dependencies. The result was a movement for imperial federation, *i.e.*, closer association. Though vociferously advocated, this movement was never widely supported in Britain or the colonies. It was never precise in its aims, and even the Imperial Federation League, founded in 1884, could not unite on a single policy. The enthusiasts argued for association in three spheres: defense, trade, and the making of foreign policy. Some wanted a single imperial navy and possibly an integrated system of land forces, supported by joint action. Others wanted intra-imperial free trade or possibly a revival of tariff preferences to ensure colonial markets for British manufactures and metropolitan markets for colonial primary products. Finally, most who desired these things (and many wanted both) agreed that some form of imperial council or parliament would be necessary to organize them. Moreover, such a representative body might be able, by bringing the colonies into consultation with Britain, to commit them to fight on its behalf during an emergency.

By 1914 none of these aims had been fully realized. In 1887 New Zealand and some Australian colonies agreed to make small contributions to the British Navy in return for the maintenance of specified naval forces in their waters, but after 1907 Australia ended these subsidies and prepared to found its own navy. Cape Colony and Natal paid unconditional subsidies from 1898, which were continued by the Union until 1921. Canada never agreed to naval contributions. Integration of land forces also proved impracticable; but considerable standardization of equipment and

organization was achieved, and the Imperial General Staff of 1909 was able, by persuasion, to improve the standard of colonial armed forces. Commercial integration also foundered. The colonies were not prepared to accept intra-imperial free trade because they wanted to protect their own nascent industries against British products. Conversely, Britain remained free-trading, despite Joseph Chamberlain's fervent campaign of 1903-06 to convert the public to protection and imperial preference. The only positive result was that Canada, Australia, and New Zealand gave British imports an advantage by raising their existing tariffs on foreign imports. Finally, the project for an imperial council failed completely. The colonies saw that Britain would dominate any such body and that representation on it would merely commit them to accepting British policies, while the United Kingdom government refused to share its authority with colonial governments.

Nonetheless, discussion of these various plans had one concrete result in the establishment of periodical conferences between Britain and the self-governing colonies, which were thus treated more as states than as dependencies. The first conference was held somewhat informally in 1887 as a by-product of the royal jubilee. The next was in 1897, also a jubilee year, but on this occasion consisted of prime ministers rather than delegates and was treated far more seriously by Joseph Chamberlain as colonial secretary. Thereafter the conferences became more or less regular, meeting in 1902, 1907, and 1911, and after 1907 they acquired the title "Imperial Conference" (see below *Landmarks of Commonwealth Growth: Evolution from Empire*).

**2. Britain and the Partition of the World.**—To most people in Britain relations with the older colonies were the substance of imperial policy before 1914. Yet in retrospect the expansion of the tropical empire during this period seems far more significant, for this generated the most acute problems of imperial policy then and later and ultimately gave the post-1945 Commonwealth its special multiracial character.

Britain was probably the most reluctant of the powers who competed for new colonies after 1880. It had no intrinsic need for new possessions and for long felt little enthusiasm for dominion over other races. But a combination of factors—problems resulting from growing contacts with other peoples and conflicts of interest with Germany, France, and other European nations in Africa and the East—eventually forced it to take a leading part in the scramble for colonies, if only to protect existing interests. The shape of the eventual empire was largely determined by the particular way in which these interests were interpreted in relation to the actions or claims of other powers.

In West Africa Britain had substantial commercial interests, yet no government made a strong stand against rival claims there until the later 1890s. The result was that although the Gold Coast and Sierra Leone acquired large hinterlands and Lagos was inflated into Nigeria, France took the lion's share of the territory in that area. In East Africa, however, where substantive British interests were minimal, Britain paradoxically made its largest gains. This was because the security of Egypt and the Suez Canal was regarded as a primary British concern, and annexation of Uganda, Kenya, the Egyptian Sudan, British Somaliland, and Zanzibar was intended to insulate Egypt from other European possessions. In Central Africa Britain again had few direct interests. But Britain was pushed on by demands from the Cape, led by Cecil Rhodes, that it should keep Central Africa open for Cape expansion. This resulted in the reservation of the area later called Rhodesia and a protectorate over Nyasaland.

In southern Asia British gains were less spectacular. Upper Burma was at last occupied in 1885 because the Burmese monarchy, long under virtual British protection, attempted to regain its freedom by associating with the French in Indochina. The remaining sultanates of Malaya were made British protectorates at various times before 1914 because the growth of "British" (in fact, largely Singapore) economic activity there required a firmer political basis than the sultans could provide. In China Britain acquired no formal colonies or protectorates in addition to Hong Kong (annexed in 1842) but took spheres of interest in the basin of the Yangtze and around Canton, adjusted the frontier of

Burma, and acquired the lease of the port of Wei-hai-wei (Wei-hai). Britain also shared extended trading rights in the "treaty ports" and had a sector in the international settlement area of Shanghai. Finally, in the Pacific, Britain was forced by demands from its colonies in Australia and New Zealand, who were deeply concerned at the sight of German, French, and United States expansion to the north, to annex southeastern New Guinea and the Cook Islands; to negotiate a protectorate over Tonga; and to form a condominium with France over the New Hebrides.

Partition had again changed the character of the British Empire. Considered as a whole its main feature was now variety. Nothing except subordination linked its disparate parts. Juridically, in addition to the older colonies acquired by "settlement" and by "conquest" (both legal rather than descriptive terms), it now contained many protectorates and protected states, all of which remained technically foreign countries though under increasingly tight imperial control. Nor had the Empire as a whole any necessary utility. The older settlement colonies were "useful" as possible allies and as a field for emigration. India was thought valuable as a vast market and because it supported a large army. A few tropical dependencies were valued because they produced commodities such as copper, tin, rubber, and vegetable oils. But many of the new colonies, and some of the older ones, were held merely to exclude some foreign power, for emotional reasons, or because they survived long after some previous function had ceased to be relevant. In short, much of the 20th-century Empire consisted of relics of transient circumstances and provided Britain with no measurable advantage. Yet, however functionless, all dependencies had to be governed; and the need to evolve techniques for governing non-European peoples, which led to the question of their ultimate future, was perhaps the main consequence of the expansion of empire after 1880.

**3. Crown Colony Government and "Native" Administration.**—The problem of administering non-European dependencies was not, of course, new; but as it happened none of the earlier British possessions provided a satisfactory model for dealing with many of the post-1880 acquisitions. Excluding the white settlement colonies the two obvious models were India and the small West Indian and West African colonies.

At first sight India seemed the more promising experiment, for there too the problem had been to rule a vast indigenous population without use of European settlers as intermediate agents of Britain. India in fact offered two contrasting models for tropical government. British India was administered by a small group of professional civil servants—the Covenanted Service, later called the Indian Civil Service—who were in "direct" contact with Indians. Although the British had adopted many Indian forms, and in particular Indian customary law in civil cases, they had ultimately remodeled the legal system, methods of tax collection, and indeed any aspect of government which it seemed desirable to change. British India was thus the classical example of "direct" administration of a non-European dependency. By contrast, much of India still consisted of partly autonomous princely states, which were either tied to Britain by treaty, as were many protectorates in other parts of the world, or were deemed to be under the paramountcy of the crown by inheritance from the Mughal emperors. This was "indirect rule." The states were nominally autonomous in internal affairs, but were closely supervised by the British, who increasingly used Indian rulers as instruments for carrying out policies conceived by the British-dominated all-Indian government. Finally, it is important to remember that until 1914 government in India was largely autocratic. The princes were in theory despots. So also was the governor-general of British India. His executive authority was limited only by a small advisory council of officials and, ultimately, by Parliament and the India Office in England. His Legislative Council (and similarly the councils set up in all the major provinces after 1861) was entirely nominated until 1892. In that year a number of quasi-elected members were added, and from 1909 both central and provincial councils had a number of genuinely elected members. But until the passing of the Government of India Act of 1919 these councils were merely advisory bodies with

no capacity to obstruct government or initiate legislation. India thus offered an example of how Britain could rule a vast Asian country through a minority of expatriates with no cost to itself either by "direct" or by "indirect" methods.

"Direct rule" similar to that in British India was applied to Ceylon early in the 19th century, but it was seldom applicable in that form, to post-1880 British acquisitions. To be successful it required a country which was rich enough to pay for an elaborate administrative machine, sufficiently sophisticated to provide a corps of literate subordinate officials, and so individualized socially that people would accept government other than through traditional local chiefs and within the framework of local custom. Conversely "indirect rule," as in princely India, demanded that indigenous states should be capable of running their own affairs under supervision and also a broader regional framework of British government to supervise them. Few post-1880 British dependencies initially fulfilled either condition. Some form of "indirect rule" was used in the Malay sultanates, in Brunei, and in Tonga. Burma could have been dealt with similarly, but it was incorporated into British India because the native dynasty refused to co-operate with Britain. But elsewhere native states were seldom strong or efficient enough to be left as protected states. Conversely, it would have been a sheer physical impossibility to construct intensive "direct" systems of government in tropical Africa or in the Pacific Islands during the first generation after annexation, for in none was there an adequate social structure or sufficient revenue, and Britain lacked a reserve of trained colonial officials to govern them.

In these colonies the problem of central government was relatively simple. All colonies and protectorates were given the basic institutions of "Crown Colony government" (an autocratic governor, an advisory executive council, and, sometimes, a nominated legislative council). But this did not solve the problem of administering the vast hinterlands of the colonial capitals where these governments sat. There the older Caribbean model was inapplicable, for the West Indies, after the emancipation of the slaves, had become quasi-European societies in which English law and administrative institutions were virtually unchanged. This had even been true of small West African colonies such as Lagos and Sierra Leone before they expanded after 1880. Now something new was needed. Early British experiments varied according to the area and its problems. South and Central Africa were special cases because of the presence of European settlers and because the British South Africa Company controlled Rhodesia. Policy was therefore to segregate Africans into "reserves" under very loose supervision, leaving government in the hands of settlers or the company. This amounted perhaps to a form of "indirect rule," but one which did little to preserve indigenous institutions or to improve African conditions; and these reserves were the roots of the apartheid (racial separation) policy later adopted by the government of the Union of South Africa. Elsewhere, in East and most of West Africa, the British at first proceeded pragmatically. Early administration aimed only to obtain recognition of British authority, to stop the slave trade, control white land speculators and labour recruiters, and collect a few taxes. Ultimately, such supervision developed into various types of "direct" administration as experience grew, as sufficient revenue became available, and as Africans were trained to work as subordinates to British officials. By 1914 this process had barely begun; by the end of colonial rule it had created intensive government by officials in most British territories in tropical Africa.

This development had a major defect: as it grew from loose supervision to intensive "direct" rule it necessarily destroyed many indigenous social and political patterns, leaving the new subjects (in colonies) and "protected persons" (in protectorates) suspended between two worlds; unable to return to their former ways but barred from a full share in their new government by the fact of alien power. It was this problem that Frederick (later Lord) Lugard attempted to solve by the administrative techniques he adopted first in Northern Nigeria from 1900 to 1906, and then, with rather less success, in Southern Nigeria from 1912 to 1919. His "system" evolved pragmatically from the fact that the amirs

of Northern Nigeria were too powerful to be tampered with too much, and were also sufficiently sophisticated to be capable of acting almost like Indian princes under British supervision. His policy, as embodied first in his *Political Memoranda* (subsequently published in 1919) and later expounded in his *Dual Mandate* (1922), was that Africans should be carefully supervised by the central British government of the colony, but that day-to-day administration should be left to "native authorities," preferably hereditary rulers. These must remain "unfettered" in the sense that they should have their own treasuries, courts, and laws, but at the same time "subordinate" in that they had to obey laws made by the colonial government, accept British advisers, and contribute part of their revenues to the central colonial treasury. Thus, Lugard's system attempted to balance African autonomy and imperial authority, to allow Africans to take an active part in their own government and preserve their identity without weakening British control or blocking attempts to "improve" them.

Lugard's principles, which may be distinguished as "Indirect Rule," marked the apex of British thought on non-European dependencies before the era of decolonization in the mid-20th century. In their full form they were applied only in Nigeria and Tanganyika, for in most other areas conditions were unsuitable, or other patterns were too well established to be discarded. But in most British colonies and in those of some other colonial powers such as Belgium, Lugard's basic assumptions were adopted as a broad rule of conduct. European rule came to be regarded, rightly or wrongly, as a moral "trust," justifiable only if it operated to the advantage of non-Europeans as well as of Europe. The primary obligation imposed by the trust consisted in protecting Africans and others from exploitation by Europeans, by preserving their land, stopping recruitment of labourers to work under semi-servile conditions, and not permitting minorities of European settlers to rule African majorities. At the same time, it meant providing amenities such as medical services and education and eliminating such "uncivilized" customs as infanticide and slavery.

In its context such a concept of colonial administration was honourable and constructive. It appeared defective only in retrospect, after it had become the assumption that the aim of colonial rule should be to train colonies for full sovereign independence. Neither "Indirect Rule" nor "trusteeship" were calculated to achieve this result. Because they presupposed an outer framework of European government and emphasized preserving indigenous institutions and established elites rather than on training non-Europeans to share in the central government of a colony on democratic principles, they tended to be a substitute for a policy of evolution toward independence. But in 1914 such criticism was virtually inconceivable. Tropical empire was still regarded as a holding operation without any foreseeable terminal date.

By 1914 the rapid expansion of the British Empire since about 1880 had, therefore, intensified trends originating in the 18th century. The original English tradition had been one of colonial autonomy under imperial supervision. Conquest of foreign colonies and annexation of new territories in Asia and Africa after about 1763 introduced the principle of nonrepresentative government in certain dependencies together with the retention of non-English systems of law and administration. Expansion after about 1880 greatly increased this variety of constitutional and administrative forms within the Empire. In 1914 the few white "dominions" formed an elite group in virtual partnership with Britain: the remaining possessions constituted the dependent empire. This was not, of course, undifferentiated. Some colonies retained representative assemblies though without ministerial systems. In India the first steps had been taken to enable Indians to share in government and legislation, and they had theoretically full equality of opportunity in the civil administration. But in 1914 it still seemed improbable that India or any of the other non-self-governing dependencies would achieve the status of the dominions within the foreseeable future. The astonishing feature of the following half century was that by the 1960s the majority of the dependent territories of the British Empire had joined the original dominions as sovereign states and equal members of the Commonwealth of Nations.

(D. K. F.)

### III. THE DEVELOPMENT OF THE COMMONWEALTH

**1. Some Important Factors.**—The Commonwealth in the mid-1960s was a voluntary organization of nations which had common interests, sentiments, traditions, and roots in the history of the British Empire. Although the association, as its name implied, rested on the consent and agreement of all participants, many of the forces, both divisive and cohesive, which had shaped its development were at work even at the height of imperial power. The Commonwealth evolved to include many races and cultures, but the essence of its structure and many of its ruling principles were developed for settlements primarily of British emigrants to North America, Australasia, and South Africa. The remarkable achievement which became the Commonwealth can perhaps be appreciated best by contrasting its history with the bitter conflict and fragmentation which brought an end to the French and the old Spanish empires.

The major determinants of Commonwealth growth were patterns of economic, political, and social development, both worldwide and within the constituent units. It is possible to isolate at least four basic forces which moved the British Empire toward an association of independent nations, and at least three forces which operated against complete fragmentation and favoured retention of certain bonds embodied in the Commonwealth.

The first divisive force in the Empire was the administrative necessity, recognized in Britain as well as in the colonies at an early date, for a measure of self-government within the dependent territories separated from the mother country by thousands of miles of land and ocean. Effective central administration of complex far-flung possessions became increasingly difficult and costly. Critical decisions could often not await confirmation from Britain.

Second among the forces leading to fragmentation of the British Empire was mounting pressure for self-government within the colonies themselves, a pressure which often combined demands for local autonomy from the middle classes with hopes of the masses for a wider franchise. Colonial insistence upon self-government was based mainly upon the simple aspirations of people to manage their own affairs, but it was strengthened by a developing liberal political philosophy expressed in the 19th century by such writers as John Stuart Mill. As most British colonies began to assume distinct identities in the minds of their citizens, a note of aggressive nationalism entered into appeals for self-government. Some immigrants to British colonies brought to their new homes a legacy of anti-imperial feeling from Ireland and the U.S., which strengthened the nationalist agitation. Colonists of non-Anglo-Saxon stock, such as French-Canadians and South African Boers, lacked even the bonds of common heritage as a cement of empire. Britain, for its part, had learned from the American colonies in 1776 to ignore nationalism only at its peril and was prepared to acquiesce to some extent in requests for greater independence.

A third divisive force within the Empire, which evolved at varying rates in different areas, was the growth of economic, social, and political links between individual British colonies and outside nations. Relations between Canada and the United States, based on proximity, began to rival in importance those between Canada and Great Britain as early as the mid-19th century. Later, two world wars greatly reduced Britain's power in the world and made parts of the Commonwealth look elsewhere for leadership. One student of the Commonwealth observed in the mid-1950s that "in the Commonwealth, all roads lead to Washington."

Finally, among the divisive forces of empire was a growing conviction of many Britons themselves that imperial relationships were, on balance, an encumbrance rather than a gain and should be terminated as soon as possible.

Because Britain, relative to its colonies, always had a developed economy, a vital cohesive force of the empire was the presence of complementary economic needs. Economic relationships took three forms: trade, flows of productive factors (labour and capital), and participation in common institutions. In most instances, economic links were voluntary and rested on mutual recognition of benefit for all partners. Trade consisted predominantly of

British exports of manufactured goods and imports of raw materials and partly finished products. Factor flows involved mainly an outward movement from Britain of labour and capital. A capital market centred in London and a monetary system based on sterling facilitated both trade and the flow of investment funds. Public awareness in Britain of dangers in over-population and the attractions of life in new countries assured a steady stream of emigration. Only after World War II did a combination of nationalist policies in some newer countries and a sudden upsurge of reverse migration to Britain bring restraints on labour flows.

A second cohesive force, which gained strength from the passage of economic resources, was acceptance throughout much of the Empire of British social, economic, educational, political, military, and legal institutions and customs. Frequently, radical colonial modifications of old-country models were carried out, such as dramatic changes in the structure of parliamentary government, but the force of British tradition was constantly invigorated, first by formal imperial links and later by informal cultural contacts of many kinds. As soon as institutions of British inspiration became established in the colonies, they became to some extent self-perpetuating. Long after imperial links were severed, political leaders, public servants, lawyers, clerics, and physicians continued to feel more comfortable with their fellows from Commonwealth countries than with foreigners. Commonwealth universities, because they were founded largely on British patterns and with British scholars, tended to turn to Britain for replacement staff and curriculum innovations. Similarly, military forces in the Commonwealth continued to accept British customs and practices even when the chain of command had been broken.

A third cohesive force in the evolving Empire-Commonwealth was recognition by most member states of major economies which might be gained from the association in important functions of nationhood, notably defense and external relations. Some members before and after independence realized clearly that even without any formal structure such as that proposed for an imperial federation savings could be made by acceptance of British or other Commonwealth military and diplomatic services, sufficient even to outweigh the costs of any apparent loss of autonomy. Early examples of cooperation were the protection afforded by the Royal Navy to the dominions and the consular functions performed by British missions for citizens of Commonwealth states. Later examples were the provision by Australia of anti-guerrilla troops to Malaya and Canadian training of Tanzanian armed forces. An aspect of this third cohesive force was a belief of smaller states, such as islands in the Caribbean, that preservation at least of minimal ties with the Commonwealth could increase international prestige and even, in certain cases, be an essential guarantee of survival in a world of voracious neo-imperial powers.

**2. Terminology.**—The term Commonwealth of Nations was used occasionally late in the 19th century to describe a new type of association which was thought to be emerging from the British Empire. It was popularized in the years before World War I, particularly by Lionel Curtis, an ardent proponent of imperial federation. Subsequently, there was a discernible movement from use of the term Empire to the term Commonwealth. To both Curtis and Gen. J. C. Smuts the words meant the same institution at different stages of evolution. In the Balfour Report of 1926, however, the "British Commonwealth of Nations" was made more exclusive than the Empire to include only the "autonomous communities within the British Empire." In the Statute of Westminster in 1931, the Balfour distinction was made explicit, and "the free association of the members of the British Commonwealth of Nations" was defined to include "the United Kingdom, the Dominion of Canada, the Commonwealth of Australia, the Dominion of New Zealand, the Union of South Africa, the Irish Free State and Newfoundland." By World War II, the "British Empire" was used by some writers and speakers to describe only the non-self-governing territories not yet possessed of full Commonwealth status. Others, including the British prime minister, Clement Attlee, treated the two terms, Empire and Commonwealth, as being still nearly indistinguishable except that the Commonwealth might be viewed as an end toward which the Em-

pire was moving. A clear change of official terminology in the United Kingdom after World War II was away from the words Empire, Imperial, and British Commonwealth, to Commonwealth of Nations or simply Commonwealth, describing all territories, those which were full sovereign members and those which were dependent. In the other nations of the Commonwealth, the adjective "British" continued to be used on some occasions, but the term "Dominion," introduced in 1907 and implying a degree of subservience, was gradually eliminated in favour of "member of the Commonwealth." The meeting of Commonwealth prime ministers in 1946 was the last important gathering to use the term British Commonwealth instead of simply Commonwealth.

#### A. LANDMARKS OF COMMONWEALTH GROWTH

**1. Evolution from Empire.**—A vision of self-governing units operating freely within some type of imperial association was seen, albeit somewhat dimly, as early as the mid-18th century by a few American leaders and subsequently in the early 19th century by reformers in the remaining British colonies, such as Robert Gourlay and Robert Baldwin in Canada, and William Charles Wentworth in Australia. The notion of a free association containing former colonies and mother country was implicit also in the classical economic writings of Adam Smith, David Ricardo, John Stuart Mill, and Thomas Malthus; the classicists argued in refutation of the mercantilist policy of strict colonial dependence on the metropolis that the most valuable and permanent bonds with colonies would be rooted in the mutual advantages of free economic relations. Elaboration of the rationale for a large measure of colonial independence was provided by Edward Gibbon Wakefield and other colonial theorists during the 19th century.

As stated above, the Durham Report of 1839 was the first extensive elaboration of the liberal imperial philosophy. A succession of actions by the British Parliament implemented most of the policies recommended in that report and laid out the path which led to the Commonwealth.

**2. Sentiment for Federation.**—The development from Empire to Commonwealth came to an important crossroads in the years around the turn of the 20th century. In Britain during the 1870s, a significant segment of opinion had begun to react against what was known as the "Little England" view that colonies should be liberated as quickly as possible both to reduce administrative costs and to maximize the potential gains from friendly unrestricted international trade. Imperialist sentiment was strengthened by visions of grandeur portrayed by Rudyard Kipling and by the realization that in the competitive scramble among great powers colonies not acquired or retained by Britain would almost certainly be annexed to another empire. Dependence upon uninhibited exchange of goods and resources among nations was seen as unrealistic in the context of late-19th-century world politics. As early as 1872 Disraeli in his Crystal Palace speech proposed closer political union within the Empire; and by the end of the century this idea had grown into a full-fledged proposal for an imperial federation (*see above, The British Empire, 1880-1914*).

Seen in retrospect, imperial federation would have been a backward step in the progress of Commonwealth development initiated by the Durham Report. The plan had little to offer the far-flung components of the Empire as they developed economically and tasted the first fruits of independence. Advocates of imperial federation recognized correctly an unresolved paradox of empire wherein self-governing states remained dependent upon a metropolis for certain vital services but did not contribute fully to their costs or participate in their performance. But the solution posed by imperial federation did not take account of the strong decentralizing forces present within the Empire, and the scheme was rejected.

In 1907 the increasing autonomy of the self-governing colonies was recognized by the official designation "dominions" and by inauguration of a series of imperial conferences wherein, on a more regular basis than before, prime ministers met on an equal footing to discuss matters of mutual interest. The imperial conferences did more to recognize an advance in status which had been achieved already than to change status through their exist-

tence; but they helped to strengthen the bonds of free association by reducing the formality of relations.

**3. Imperial Defense.**—A major unanswered question in the imperial formula of the Durham Report plagued the first imperial conferences. This was, for how long and under what arrangements for reimbursement and control should the metropolitan power continue to conduct the external relations of self-governing colonies? A central issue related to this question concerned the organization of imperial military power. All the dominions undertook to form their own militia forces after gaining responsible government, but in effect they remained dependent for protection from major external aggression upon the Royal Navy to which they made no regular contribution and over which they had no control. Moreover, the function which colonial forces might have in offensive action was unclear. Both Canada and the Australian colonies sent contingents to the South African War in 1899, an imperial struggle which clearly was not of their making. But some colonists, such as Henri Bourassa in Canada looking to the possibility of a wider world conflagration, detected and pointed out vociferously a serious anomaly in self-governing states finding themselves at war by act of a parliament in which they had no voice. The dominions did assist sporadically with naval costs prior to World War I; and Australia even began its own fleet. But the imperial defense question remained unanswered and politically volatile; it symbolized a fundamental problem in the change from Empire to Commonwealth, that of reconciling centralized performance of certain functions with effective autonomy for the units.

**4. The Sterling Exchange Standard.**—Like most other features of the Commonwealth, the sterling area originated early in the 19th century. Just as Britain provided most of the foreign trade and virtually all of the external capital for its colonies, with the exception of Canada, it offered also its own currency and models for financial institutions. Equilibrium in the imperial economic system was maintained roughly by an outflow of sterling from Britain in payment for raw commodities and by investment, matched by an inflow of sterling for manufactured goods, services, and interest on debt. As the colonial financial and monetary systems evolved, they remained heavily dependent upon the mother country for initiative and control. In part, close links of economic institutions were a condition imposed by the major trading partner and supplier of capital, but in part also they were an aspect of the more general social and cultural dependence. Britain provided large numbers of bankers and financiers to accompany its trade and capital, and these men looked to London for support and as a safe repository for reserve funds.

Only Canada, over which the United States exerted the dominant economic influence from an early date, failed to mesh its monetary and financial system tightly with that of Britain. Even after the colonies in Australia, New Zealand, and South Africa had gained unquestioned self-government, they maintained substantial reserves in London and strict convertibility with sterling. The sterling exchange standard was not an artificial creation of empire but a natural and voluntary outgrowth of a commercial and investment system based in London. The usefulness of this particular feature of imperial relations was demonstrated by its adoption in non-colonies and its continuation into the Commonwealth.

## B. TWO WORLD WARS AND THEIR AFTERMATH

**1. World War I.**—World War I brought major changes in the developing Commonwealth. First, as a result of their war efforts, the dominions took important steps toward achieving separate national identities. The experience of full mobilization, substantial losses on the battlefield, and pride in the gallantry of their fighting men combined to generate strong patriotic consciousness in these new nations which had been created not long before from aggregations of separate colonies. The economic stimulus of wartime needs helped also to accelerate industrialization of predominantly staples-producing areas and strengthened the relative power of the newer nations within the empire. Because of their active participation in the conflict and their enhanced economic position the dominions could no longer be taken for granted in international affairs. Sharp debate over military conscription and imperial soli-

darity erupted within all the dominions, but even in the heat of controversy the loyalty of all disputants to their homelands as well as to Britain and the empire was notable. One manifestation of increasing national consciousness was pressure from all the dominions for their troops to serve in distinct units under their own officers rather than as components of the imperial forces.

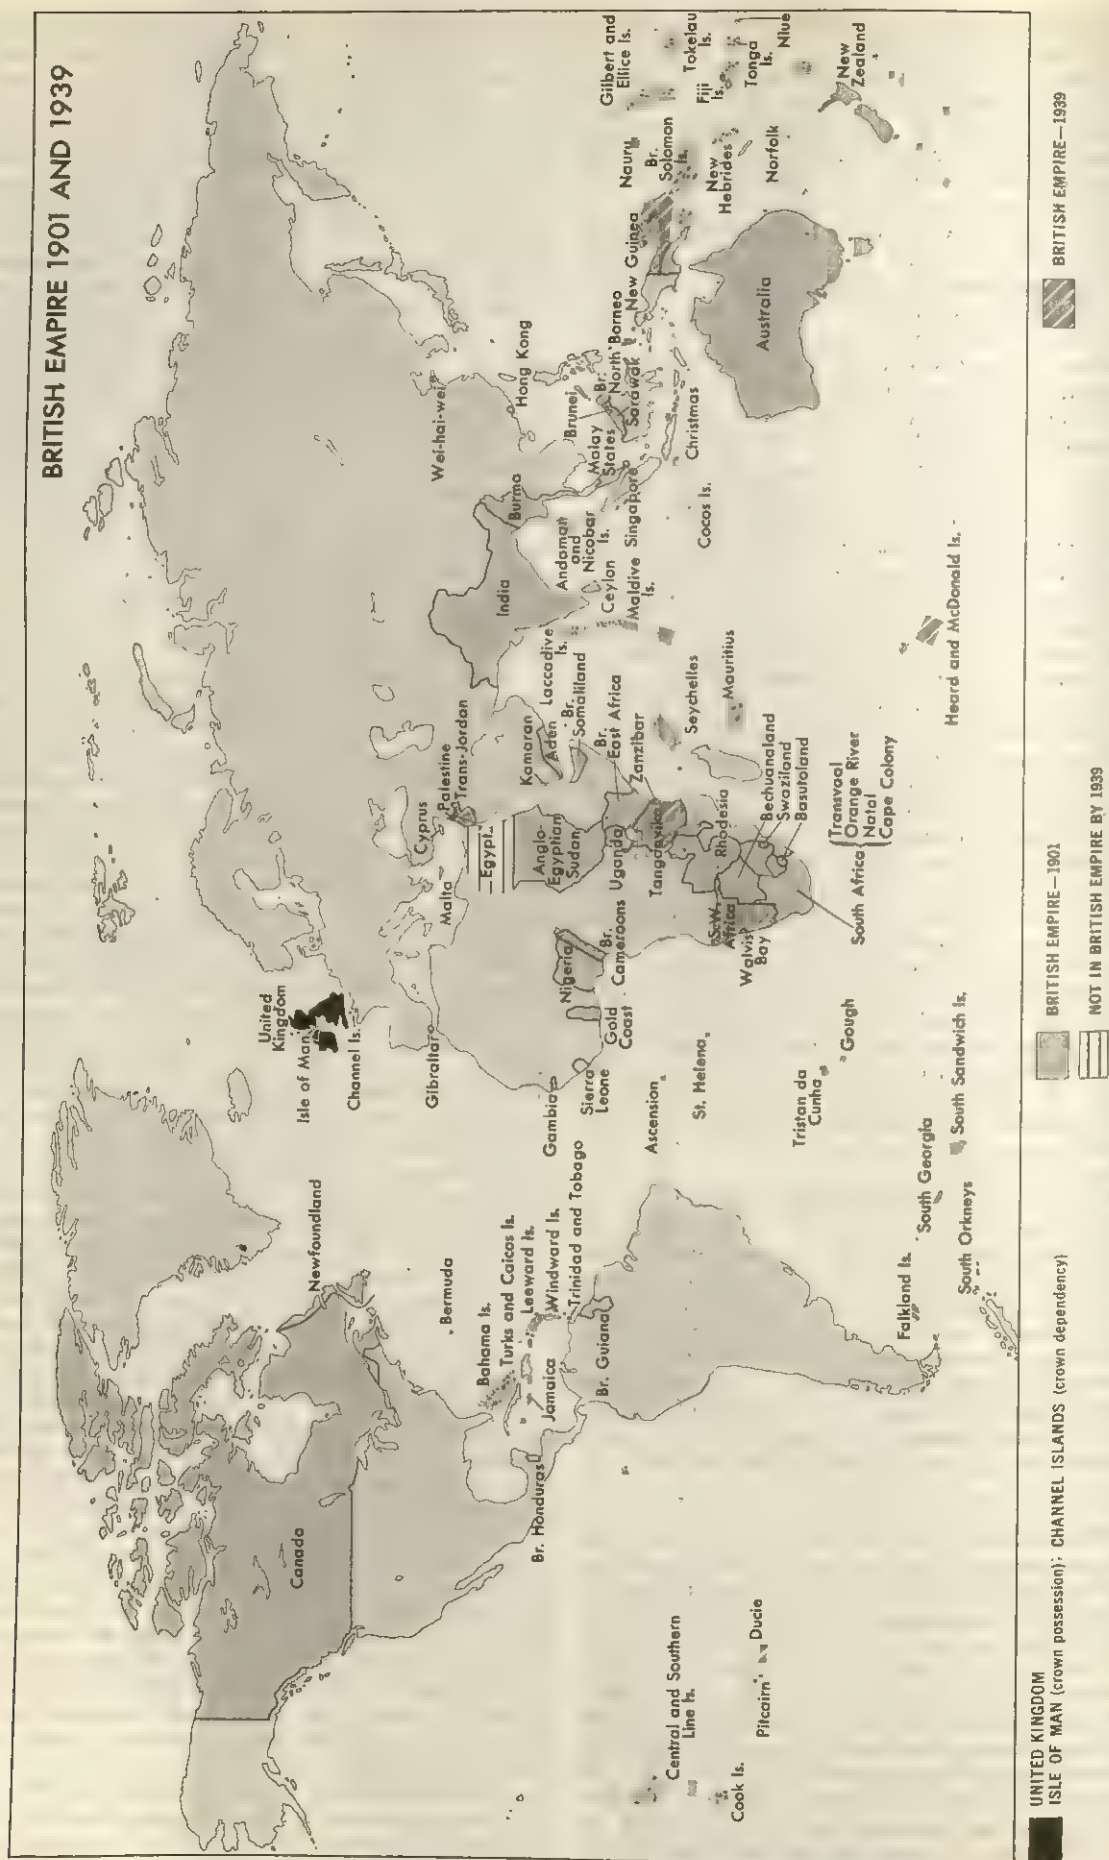

The second major change in the Commonwealth brought about by World War I was an enhanced status for the dominions in relation to Great Britain. Recognition by the mother country of a new status for the dominions akin to partnership came with the conversion of the British War Cabinet during critical periods of 1917-18 into what was called the "Imperial War Cabinet." This new council was similar to the old imperial conferences and was not a cabinet in any real sense in that it was not responsible to any single legislature. But the Imperial War Cabinet did give the most energetic and vocal dominion leaders, Sir Robert Borden from Canada, William Hughes from Australia, and Jan Smuts from South Africa, an opportunity to speak vigorously on matters of joint concern. The principle of near equality was continued at the Versailles Peace Conference where a British Empire Peace Delegation carried on negotiation and where the dominions as well as Great Britain signed the Peace Treaty. The approach of the dominions to full sovereignty was recognized formally yet once more when the dominions with India were granted independent status in the League of Nations.

The major unanswered questions in Commonwealth relations after World War I concerned the implications of the new status gained by members and the form which relations of dominions with other countries now should take. Before the war, the dominions had occasionally been accorded privileges analogous to those of sovereign states, such as separate membership at international conferences, but they had depended heavily on the British government for such critical tasks as negotiation of treaties and for representation abroad. Developments during the war had produced a practice which the British prime minister, David Lloyd George, termed "joint responsibility" for foreign policy, epitomized by the British Empire delegations at Versailles and the Washington Conference on Limitation of Naval Armament in 1921-22. It remained to be seen whether this practice could stand the long-term test of peace.

The need for more real initiative by the dominions in their own external affairs and the impossibility of maintaining a true joint imperial foreign policy during peacetime were demonstrated forcibly soon after the war by what was called the Chanak incident. In 1922 the dominions were asked to make commitments of troops in support of Britain over a complex controversy with Turkey concerning the Dardanelles. The dominions were not consulted fully at all stages of the complicated events preceding the crisis, and the Canadians and South Africans were doubtful both about their interest in the matter and about the desirability of their involvement in any circumstances. Although the crisis subsided without hostilities, the Chanak incident made it abundantly clear that not only were the dual objectives of consultation and consensus impossible to achieve where issues of foreign relations were complicated and the urgency of world war absent, but also that the notion was unrealistic of a single foreign policy for a grouping as large as the Commonwealth governed by many independent locally responsible legislatures. The divergence of viewpoints among the dominions and the United Kingdom over foreign policy was increased markedly during the 1920s by the election of such aggressive nationalist prime ministers as William Lyon Mackenzie King in Canada and James Hertzog in South Africa. Moreover, establishment by treaty of the Irish Free State in 1921 created within the Commonwealth a nation with status equivalent to the dominions but with little affection for the association and with firm expectations of ultimate independence. In 1920 a portent of an impending new autonomy in foreign policy was an announcement in the Canadian Parliament of plans for separate diplomatic representation in the U.S.

**2. Constitutional Advance: Statute of Westminster.**—Under mounting nationalist pressures, new constitutional principles and practices developed during the 1920s which affected relations of Commonwealth members with other countries and among them-

selves. In 1923 Mackenzie King insisted that a Canadian minister alone sign a Halibut Fishery Treaty with the United States, and the Imperial Conference of that year recognized this important precedent by affirming that henceforth all the dominions could negotiate treaties on their own behalf with the sole stipulation that they inform other interested Commonwealth members of their intentions. An incident occurred in Canada in 1926 which prompted more urgent questioning of the relationship between that dominion and Great Britain. During a political crisis, the governor-general, the representative of the crown in Canada, refused to accept advice of the then prime minister Mackenzie King, to dissolve Parliament and call an election. Instead, he summoned the minority leader who attempted unsuccessfully to govern the country. In the election which followed, Mackenzie King was reelected with a platform of constitutional reform.

The Imperial Conference of 1926 took account of recent developments and produced a milestone in the evolution of the Commonwealth, the report of the Inter-Imperial Relations Committee known as the Balfour Report. This document recognized formally the full autonomy and international equality of status of the dominions and the mother country; it also emphasized the desirability of continued mutual cooperation in the Commonwealth on the clear understanding that Britain was the senior partner. The report stated that equality of status, so far as Britain and the dominions were concerned, was the root principle governing inter-imperial relations. But the principles of equality and similarity, appropriate to status, did not universally extend to function. The report outlined aspects of the flexible machinery of Commonwealth relations and described unequivocally for the benefit of Canada the role of the crown representative, stating that the governor-general of a dominion was the representative of the crown, holding in all essential respects the same position in relation to the administration of public affairs in the dominion as was held by His Majesty the King in Great Britain. He was not the representative or agent of His Majesty's government in Great Britain or of any department of that government. Henceforth, official channels of communication among Commonwealth members would be between government and government direct. The report concluded by recommending that a special conference propose detailed changes in existing constitutional law to recognize formally the new status of Commonwealth members.

The Balfour Report was received in each of the dominions with a level of enthusiasm roughly proportionate to the degree of actual independence already attained at that time. Detailed proposals of the special conference for legal implementation of the report were first approved by the Imperial Conference of 1931 and then embodied by the British Parliament in the Statute of Westminster of that year. The statute, which amounted to a self-denying ordinance, set forth the terms of autonomy as requested by the dominions. It began by observing that because dominions were united by a common allegiance to the crown they had a common interest in the succession, and in royal style and titles. It went on specifically to grant legislative autonomy to the dominions, rights to pass legislation having extraterritorial operation, and exemption from British law except with their own consent. Although the constitutions of the dominions remained technically unaffected by the Statute of Westminster, embodied as they were in acts of the British Parliament, in a real sense the dominions gained effective sovereignty thereby.

**3. Economic Depression.**—The 1930s were an inauspicious decade for the Commonwealth to inaugurate its new constitutional structure. Problems of economic depression dominated the Western world throughout the period, and members, like other nations, were compelled to concentrate on finding solutions to internal difficulties, paying scant attention to complex aspects of international relations. Newfoundland was compelled by financial difficulties even to give up dominion status for government by commission which ended only when a plebiscite in 1948 approved union with Canada as the tenth province. Few steps were taken toward a new role for the Commonwealth as an association of positive co-operation or by individual members toward distinctive foreign policies. A conference at Ottawa in 1932 did work out a Com-

monwealth-oriented system of bilateral tariff concessions, but this was little more than a collection of *ad hoc* anti-depression measures among Britain and its major trading partners.

Even the long-standing bond of sterling, which had returned to the gold standard in 1925 at an unrealistic prewar rate of conversion, lost strength and was forced to retreat from convertibility with gold in 1931. A more formal "sterling bloc" then came into being, made up of countries the currencies of which remained tied to the pound sterling. These included principally the Commonwealth, except Canada, and a few other countries with a predominance of trade with Britain. But an unmistakable weakening in the role of sterling was a result of the depression.

Led by Canada, the Irish Free State, and South Africa, the dominions began in the 1930s to establish representatives in foreign capitals, but they did not inaugurate distinctive independent courses of international action. Questions as to the divisibility of the crown and possible conflicting acts of Commonwealth members in such crucial matters as declarations of war, as to the feasibility of a distinct and unified Commonwealth foreign policy, and as to the potential of the Commonwealth to offer continuing benefits to all members, remained unanswered during the 1930s. The Commonwealth neither collectively nor through its parts was able to answer effectively any of the three major challenges of the decade: depression, the decline of the League of Nations, or the gathering storm clouds of war.

**4. The Abdication.**—Two occurrences of special significance for the Commonwealth during the 1930s were the abdication of King Edward VIII in 1936 and increasing restlessness within the Irish Free State. Concerning the abdication, the prime minister, Stanley Baldwin, made clear the firm intention of the British Parliament to observe the principles set forth in the Statute of Westminster that the crown was a vital symbol of the Commonwealth and that the dominions had an equal interest in the succession to the crown. Accordingly, he obtained prior approval for his actions from all the dominions.

**5. The Partition of Ireland.**—Events in the Irish Free State were the conclusion of the least happy aspect of Commonwealth development. Several hundred years of a harsh British policy of coercion toward Ireland had by the 1930s left a substantial legacy of bitterness. This was not diminished by the partition of the island in 1921 and the creation of the southern portion as the Irish Free State with dominion status. Alone among the dominions, southern Ireland gained its place within the Commonwealth without its own consent. Eamon de Valera, the prime minister during the 1930s, worked steadily to alter this constitutional position; he abolished the oath of allegiance, appeals to the Privy Council, and the governor-generalship. By 1936 he had succeeded in obtaining what was effectively a republic, a step on the road to Ireland's formal secession from the Commonwealth in 1949. The ultimate grant of dominion status, a constitutional form predicated upon friendship and free cooperation, had been extended too late to succeed. The experience gained from Ireland's stormy path to independence influenced Britain's attitudes toward the aspirations of other dependencies after World War II.

**6. World War II.**—The outbreak of war in 1939 settled several questions of Commonwealth relations. At the outset, one dominion, Eire (Ireland), remained neutral, while another, Canada, declared its entry several days after Britain. The possibility of radical divisibility of the crown and of foreign policy was demonstrated forcibly. Just as had its predecessor 25 years before, World War II caused dramatic changes in the Commonwealth, both by altering the pattern of relations in the association and by accelerating economic, political, and social change within its members. A particularly noteworthy development was the recognition of the U.S. by some of the members of the Commonwealth as a focus at least as significant as Britain. Substantial contributions by the U.S. to the war effort, in the early years through "lend-lease" and later through direct participation, guaranteed its position of prominence. To Canada a paramount place for the U.S. in external relations was not new, but for Australia and New Zealand, left for the first time during the war without the protection of the British Navy, it was novel and thought-provoking. This

turn in the Commonwealth toward the U.S. was the result of the overwhelming military and economic power of the United States in the war and of the opportunities, absent in earlier conflicts, for individual members now with their own diplomatic service to plead their own cases in foreign capitals. Intra-Commonwealth consultation and cooperation did continue during the war, aided by improved means of communication and transportation, but the old structure was tempered by the new relationships. Despite proposals for closer formal Commonwealth links, no Imperial War Cabinet or similar constitutional innovation was attempted.

At the end of the war many in Britain continued to look to the Commonwealth as a means of retaining power and prestige in the face of a shrinking Empire. Australia and New Zealand hoped for continued cooperative defense, although their confidence was shaken in the very principle of a dependent military status. South Africa looked to the predominantly white Commonwealth for potential support of its racial policies. But no single proposal for a revised Commonwealth mechanism seemed to answer all of these needs, to take account of the manifold changes which had occurred, or to overcome long-standing fears among members of loss of precious sovereignty through more formal arrangements. Hopes for the new United Nations seemed momentarily to lessen the need for a revitalized and stronger Commonwealth. None of the members found the Commonwealth a burden, but neither did they fasten upon it great hopes. The divisions of Commonwealth members over even such fundamental questions as the form of the United Nations Charter and the peace treaty were demonstrated at the San Francisco and Paris conferences of 1945 and 1946.

**7. The Multiracial Commonwealth.**—The rapid devolution of imperial power by Great Britain was the most significant development of the Commonwealth after World War II. The gradual progress of the white dominions toward self-government had begun early in the 19th century and had proceeded slowly on the principle that British emigrants could legitimately be expected to recreate the political institutions of the old country in their new homes. In the late 1940s, the pace changed rapidly and a pattern was established for Britain to grant autonomy to its colonies voluntarily and in a cordial atmosphere of friendship. It may be that in transferring authority to its possessions Britain was merely pursuing self-interest and bowing to the inevitable. But at least it generally did this with dignity and good grace and in such a way that the Commonwealth could be preserved as an institution and strengthened.

The prime ministers' meeting of 1948 ushered in a new era for the Commonwealth when India, Pakistan, and Ceylon became the first members with sovereign populations of non-European descent. A form of political representation had been extended to India as early as 1892, but the British rulers had remained extremely skeptical about the desirability of introducing responsible parliamentary institutions to the nonwhite Empire. On the Indian subcontinent the problem of devising a form of government which would safeguard the Muslim minority from the Hindu majority added to British unease about the practicability of self-rule. In 1940 the Muslim League proclaimed at Lahore that the only solution to the problem of communalism was the creation of a separate nation of Pakistan. By the end of the war, Britain came to accept this argument. The postwar Labour government adopted the principles both of self-government and of partition, and it transferred autonomy to the two new nations of India and Pakistan in August 1947. The decision about membership in the Commonwealth was left to the new states, and in both cases the decision was affirmative. The peaceful expansion of the Commonwealth made possible its continuance.

Inevitably this growth of the Commonwealth brought change. Although such ill-defined features of the association as dominion status and allegiance to the crown were seen by most of the older members as pleasant sentimental bonds which did not impinge upon autonomy in any way, this view could not be held in Asia where most memories, at least among the educated minority, were of domination rather than of beneficent parenthood and where national heritage was viewed as preceding by far the British arrival. Consequently, in January 1947, the Indian Constituent Assembly

decided unequivocally that the new nation should become a sovereign independent state rather than a dominion. When Burma followed India to self-government in 1948, it exceeded the example set by India and proclaimed not only complete autonomy but also separation from the Commonwealth. Ceylon, which had obtained representative institutions in 1931 and responsible government in 1946, chose not to go so far as India when it gained full independence in 1948 and accepted dominion status. By an agreement between Britain and Egypt in 1953 the Sudan was given the right to decide whether to join Egypt or become independent, and in 1956 it chose to become a republic and a member of the Arab League, outside the Commonwealth. The problem of defining citizenship in the postwar Commonwealth framework was met by the British Nationality Act of 1948. This statute, and others like it in other Commonwealth states, established local nationality as the basis of Commonwealth citizenship.

The question of whether the republican form of government could be consistent with the principles of the Commonwealth was examined by the Commonwealth prime ministers at a meeting in London in 1949. Agreement was reached once again that the Commonwealth should remain flexible and that it be modified to take account of the altered conditions of its members, in the words of the conference communiqué "to strengthen its unity of purpose, while adapting its organization and procedures to changing circumstances." The meeting acknowledged India's intention of becoming a republic and declared that the governments of the other countries of the Commonwealth, the basis of whose membership of the Commonwealth was not thereby changed, accepted and recognized India's continuing membership in the organization. It was recorded that the government of India had declared and affirmed India's desire to continue its full membership in the Commonwealth of Nations and its acceptance of the king as the symbol of the free association of its independent member nations and, as such, the head of the Commonwealth. Whereas in the 1930s republicanism was viewed as tantamount to secession from the Commonwealth, it was now shown to be fully compatible.

The new nations of Asia brought to the Commonwealth some unhappy memories of colonial domination, bitter rivalries among themselves such as the acrimonious dispute between India and Pakistan over Kashmir, and strong views on such matters as the continued devolution of power by Britain to other colonies, and the racial policy of an older member, South Africa. The "old" British Commonwealth had given way to a "new" Commonwealth no longer British in name, sentiment, or national origin of the majority of inhabitants. The new members accepted certain vital political features in common with the old members: parliamentary government with the cabinet system and opposing parties, respect for the common law, and a proclivity for federalism. But the new Commonwealth had within it sharp elements of diversity, not only differences of race and colour but also of language, level of economic development, relative size of members, and outlook on world problems. The greatest challenge to the Commonwealth after World War II was assimilation of these elements of diversity.

**8. Arrangements for Mutual Security.**—As the Commonwealth grew larger and more heterogeneous in the uncertain postwar world, the attraction of alternative regional and other international associations increased both to new members and to old. Mindful of the prewar situation in which Nazi Germany had been able to defeat countries one by one, Britain itself began to think of some sort of "western union" of European states. The North Atlantic Treaty in 1949, to which Britain and Canada were signatories, was the first in a series of new "cold war" alliances. It was followed in 1951 by the Pacific Security Agreement in which Australia and New Zealand joined, by the Southeast Asia Treaty in 1954 which linked Britain, Pakistan, Australia, and New Zealand, and by the Baghdad Pact in 1955 signed by Britain and Pakistan. These agreements, besides directing the attention of Commonwealth members outside the association to strengthen their defense, confirmed the continuing influence upon the Commonwealth of the United States.

While most of the older Commonwealth members and some of the new sought postwar security in external defense agreements,

several newer members moved toward policies of nonalignment. India in particular, after an initial period of alignment with the older Commonwealth members, adopted a position of aloofness from mutual security treaties. During the first years of independence, India found much in common with the external policies of the West in the developing cold war, but by the mid-1950s it had moved to a position of proclaimed nonidentification either with East or West. India's independence from Western views was demonstrated by its condemnation of the United Nations advance beyond the 38th parallel in Korea, by its pressure for UN recognition of Communist China, and by its opposition to the Southeast Asia Treaty. India was openly critical of what it considered underrepresentation of Asia on the United Nations Security Council and what it feared might be incipient Western neocolonialism in support of such Asian leaders as Bao Dai in Indochina, Chiang Kai-shek in Formosa, and Syngman Rhee in Korea. Even after relations between India and China had deteriorated following Chinese border incursions, India held to its policy of nonalignment.

What was striking about India's steadfast independence of view was its continued strong support for the Commonwealth. In 1952, at a time of open disagreement between India and several of the other Commonwealth members, the Indian prime minister, Jawaharlal Nehru, explained the situation simply. The Commonwealth, he said, still had "bonds which are of advantage to us." The association had demonstrated once again its extraordinary flexibility and its continued attraction even for members with sharply conflicting views on world affairs. In foreign affairs J. D. B. Miller's description of the postwar Commonwealth as a "concert of convenience" seems specially apt.

**9. Development of the Sterling Area.**—The sterling area was formed during World War II in response to urgent needs for a successor to the prewar sterling bloc. At the outbreak of hostilities the British Treasury was given authority over all securities marketable abroad, gold, and foreign exchange in Britain; and in 1940 the sterling area was established as a group of states within which monetary transactions would be free but outside of which the new controls would apply. The Exchange Equalization Account in London was charged to hold the foreign exchange reserves of Britain, the colonial territories, and other members of the area; participants received sterling credits for the foreign currency they provided. Membership of the area fluctuated slightly over the war years but remained roughly the same as the old sterling bloc. By war's end the problem which dominated the area was the presence of large so-called sterling balances in London to the account of various members; these were the result of repeated deficit payments balances incurred by Britain for war costs financed with payments surpluses of other area members. The nanced with payments surpluses of other area members. The short-term United Kingdom liabilities of more than £3,000,000,000 in 1945 in the face of reduced British foreign investments and the dislocated export markets constituted a serious challenge to the sterling area.

An attempt was made by the United Kingdom immediately after the war to reduce the wartime restrictions of the sterling area, in recognition of promises to the United States to eliminate as soon as possible discriminatory treatment in international commerce. In 1947, in fulfillment of the terms of a major United States loan, convertibility of sterling with other currencies was reintroduced and was followed by a rapid outflow of dollar reserves. Free exchange had to be terminated after only five weeks when it became clear that the British economy had not recovered to the point where the backlog of sterling area demands for foreign currency could be filled and an equilibrium balance of payments maintained at existing exchange rates. The sterling area weathered the crisis of the return of controls, and even Ireland, a former dependency now possessed of full and vigorous political independence, remained a strict adherent to the area principles with its domestic currency tied to levels of sterling reserves in London. The postwar currency crisis illustrated clearly that the roots of the sterling area, as of so many other Commonwealth institutions, rested by this time solely in the self-interest of members, in this case their continuing high volume of trade with Britain and their firm desire to maintain currency respectability.

Two fundamental problems that still faced the sterling area in 1947 revolved around the very form and conception of the Commonwealth itself. The first concerned the policy and decision-making process in the area and was highlighted by a devaluation of the pound in 1949. Because of the need for absolute secrecy prior to this action to forestall speculators, the United Kingdom did not undertake prior consultation with area members. The reasonableness of the policy and its implementation was not seriously questioned, but an obvious anomaly remained of sovereign states having their monetary destinies determined wholly by another nation without discussion or participation. Attempts were made thereafter by Britain at least to increase the flow of information about sterling area affairs; a Sterling Area Statistical Committee had been established by the Treasury in 1947, and the United Kingdom Cabinet Office formed a Commonwealth Liaison Committee. But the basic question of how to bring about joint decision making where Commonwealth members shared British institutions, a question with roots in the 19th century, remained unanswered.

The second major problem of the sterling area was the continued existence of substantial sterling balances to the credit of members. This problem was gradually alleviated by the rapid economic recovery of Britain which permitted it to approach again a net equilibrium balance of payments. Moreover, the continued dominance by Britain of the international trade of most area members and its reappearance as an important source of foreign capital helped to maintain economic cohesiveness within the area. A gradual restoration of confidence in sterling as a satisfactory international currency took place.

**10. Strength in Diversity.**—During the 1950s and 1960s, it became clear that although many of the traditional unifying forces of earlier years had either declined substantially in importance or disappeared, the Commonwealth remained a viable institution. The old notion of unity in common allegiance to the crown lost meaning as more and more members became republics, and homogeneity of political institutions diminished rapidly as one-party governments evolved in most of the newer members. Economic, cultural, and military ties continued to diminish in importance as some members moved toward greater autonomy and others developed stronger links with non-Commonwealth nations. Nevertheless, the Commonwealth survived in the 1960s for the same reason it had been created: because in the eyes of members its benefits exceeded its costs. The difference now was in the nature of those benefits and costs.

**11. Currency, Trade, Investment, Migration, and Economic Growth.**—By the mid-1950s it was apparent that the sterling area had weathered successfully the wartime storm. The large sterling balances built up in London were gradually reduced to a "stable" level desired by their owners, many of whom were central monetary and financial institutions in sterling area countries. The economic recovery of Britain and restoration of faith in London as a financial centre permitted convertibility of sterling on current account to be reintroduced by the end of 1958. London retained its well-developed capital market and remained a relatively safe and convenient location for smaller countries to hold reserves against balance of payments deficits and other emergencies in a form which was both income-producing and readily convertible into foreign currencies or gold. By continuing to act as banker for other nations, Britain accepted the risk of sudden runs on its own reserves of foreign currency when the reserves of other sterling area members were called upon, but it minimized this risk through the number and diversity of its foreign creditors. Britain took steps to guard against major emergencies by acquiring secondary foreign currency reserves and various lines of credit; in 1956 these reserves were mobilized convincingly to forestall a crisis of confidence resulting from the Suez landings. Stability of sterling against speculative flows was safeguarded further by "gold pool" agreements among the United States, West Germany, Great Britain, France, Italy, Switzerland, Belgium, and the Netherlands; by reciprocal or "swap" arrangements with several other countries; and by the European Monetary Agreement.

Several factors combined to bring about a reduction in the proportion of inter-member trade of Commonwealth countries

during the 1950s and 1960s. First, the strengthening of sterling as an international currency permitted a relaxation of trade restriction throughout the area and a redirection of trade into more natural channels. Second, wartime inflation reduced substantially the significance of certain specific preferential tariffs erected by the 1932 Ottawa agreements. Third, increasing maturity diminished the dependence of newer Commonwealth states upon the old bilateral trade relationships with Britain of raw materials for manufactured goods. On the one hand Britain reached a limit as a consumer of staple products, and on the other it faced an increasing competitive disadvantage with industrial rivals such as the U.S. and Japan in the sale of various manufactured goods. In a few instances parts of the Commonwealth, notably Australia, Canada, and Hong Kong, became important rivals for Britain in markets for such major manufactured export items as textiles.

The only Commonwealth countries which did not experience a decline during the 1950s in the proportion of their exports destined for other Commonwealth areas were relatively small economies which remained heavily dependent in many respects upon the United Kingdom: Hong Kong, Mauritius, Sarawak, Malaya, Singapore, and Cyprus. Sharp declines in intra-Commonwealth exports took place in all countries which during the 1950s still contributed the bulk of intra-Commonwealth exports. The United Kingdom was by a wide margin the major originator of intra-Commonwealth exports, providing about a third of the total, yet the share of its own exports destined for the Commonwealth fell from about 45% to 40% over the decade. Proportional declines in exports to the Commonwealth took place in countries regardless of their current level of export dependence upon the Commonwealth: between 1948 and 1959, the proportion of Australian exports fell from 61.1 to 43.8%, Canadian from 32.5 to 20.8%, and Indian from 52.8 to 45.1%, of their respective total exports.

The dependence of Commonwealth countries upon each other for imports experienced the same downward trend proportionally as did export dependence. Between the years 1948 and 1959 the only members whose share of total imports coming from the Commonwealth did not decline were Malaya, Pakistan, and the United Kingdom. As with exports the starting level of dependence also varied widely; among the older members, Australia's proportion of Commonwealth imports fell from 68 to 51.5% while Canada's declined from 18.4 to 14.8%.

Although imports and exports both illustrated a weakening of trade interrelationships in the Commonwealth, they also revealed the continuing existence of these ties at significant levels and the sustained dominance of Britain as the hub of the trading wheel.

Restoration of Britain's ability to supply development capital for the Commonwealth after World War II was an important factor in the continuation of close Commonwealth economic ties. It is estimated that between 1945 and 1965 approximately 60% of external investment within the sterling Commonwealth came from the United Kingdom, as compared with 20% from the United States and 11% from the International Bank for Reconstruction and Development (the World Bank). During this period some £2,500,000,000 was invested by Britain in the Commonwealth, and during the second decade the average annual rate of investment was more than £150,000,000. The transfer of private capital, as in the past, took two forms: direct investment by United Kingdom companies in branches, subsidiaries, and associates; and portfolio investment by British residents in Commonwealth securities. The largest recipients of private direct investment by Britain continued to be the old dominions, but the newer Commonwealth countries also made substantial gains. The relative significance of the investment to recipient countries varied: in 1961 British investment was only 14% of total foreign investment in Canada, but over the five years ending in 1963-64 the United Kingdom provided nearly half of the total overseas investment in Australian companies. The bulk of private direct investment was for manufacturing industry.

Although still of significant magnitude, British portfolio investment in the Commonwealth decreased substantially in proportion after World War II. A number of factors help to explain this change. First, funds for construction of major public works

in Commonwealth countries, which before the war typically had come from sale of securities on the London market, came now more and more from international organizations or by means of bilateral intergovernmental agreements. Secondly, private businesses in the Commonwealth increasingly tended to accomplish growth through reinvestment of profits or access to a local capital market rather than through issue of new securities abroad. Thirdly, with the devolution of power and the transformation of Empire to Commonwealth, British private portfolio investors became less certain about the profit expectations abroad and about the impact of political change upon the safety of their investment. The Commonwealth Development Finance Company was established in 1953 as a cooperative venture between the British government and private business to act as a channel for private investment funds in the Commonwealth. By the late 1960s this company had investments and commitments of over £31,000,000.

The postwar phenomenon of large-scale economic aid from the more developed to the less developed nations of the world had a significant impact on the Commonwealth. The Marshall Plan beginning in the 1940s made possible both the rapid recovery of Britain and the partial release of the large sterling balances in London for use in the Commonwealth. Subsequently, an increasing number of assistance programs by the United States and other Western nations came to include the newer Commonwealth countries as they gained their independence. Britain itself became a major provider of aid to the Commonwealth, both to its dependent territories and to the independent states. The Colombo Plan, which had its origins in 1950, became a scheme centred roughly upon the Commonwealth whereby the U.S. and the wealthier members agreed to provide coordinated development assistance for the countries of South and Southeast Asia. During the 1950s roughly £2,300,000,000 were made available through the Colombo Plan, the United States contributing the equivalent of more than £2,000,000,000, the United Kingdom £150,000,000, Canada £125,000,000, Australia £31,000,000, and New Zealand £9,000,000.

Intra-Commonwealth migration of labour after the war was principally in two directions, from Great Britain to the former dominions and from the Asian, African, and Caribbean members to Britain. The former dominions were able to add about 0.5% to their population growth rates through immigration, Australia in particular gaining from the extension of assisted passages not only to Britons but to other Europeans as well. Immigration to Britain between 1951 and 1961 consisted of approximately 150,000 aliens, 200,000 Irish, and 300,000 Commonwealth citizens. The number was matched almost exactly by the outflow from Britain. Commonwealth immigration to Britain declined after the passing of the Commonwealth Immigrants Act in April 1962.

A cause for continued concern in the Commonwealth after World War II was the relatively disappointing economic performance in the less developed members despite the large amounts of investment and direct assistance extended to them. Absolute growth rates in the poor nations seldom exceeded even the modest rates in the rich nations, and because in the former the population increased at a very rapid rate, the gap in per capita incomes between the two groups became steadily wider. Specially high birth rates and low death rates were substantial obstacles to improvement in standards of living for the developing countries of the Commonwealth. By most estimates during the 1960s the average per capita real income in the United Kingdom and the former dominions was more than ten times that in the new countries of Asia and Africa. The growing disparity of wealth in the Commonwealth on the one hand raised concern about the possibility of a continued communality of interest; but on the other hand this was viewed as a major challenge to give continued purpose and meaning to the organization.

**12. Suez, the Common Market, and Restriction of Migration.**—Three not unconnected events placed special strains upon the Commonwealth relationship in the postwar years. The first was the Suez crisis, the second was Britain's symbolic decision to apply for membership in the European Economic Community (Common Market), and the third was a restriction on the traditional free flow of Commonwealth migration to Britain.

The British-French action at Suez in 1956, demonstrating the British government's approval of the unilateral use of force to settle international differences, destroyed the appearance of what was thought by many spokesmen in the Commonwealth to be a consensus concerning the conduct of international relations. It raised grave doubts for newly independent Commonwealth countries about the disappearance of Britain's imperial designs and about whether by maintaining any links whatsoever with Britain they opened themselves to potential neocolonialist aggression and loss of sovereignty. Britain's action also shattered the notion that significant actions in foreign affairs by Commonwealth members would always be preceded by consultation. Specific reactions of Commonwealth countries to the Suez intervention varied. Australia and New Zealand, which were specially concerned about the security of the Suez Canal, supported Britain in its action; but they were alone in the Commonwealth. Leaders of other member states saw the landings as a return to the gunboat diplomacy and imperialism which the Commonwealth had been designed to supplant. Indians and Canadians alike joined in condemning this violation of the United Nations Charter and of the sovereign rights of an independent state. In Britain, although opinion was sharply divided over Suez, the net effect of the controversy seems to have been a weakening of enthusiasm for the Commonwealth. Resentment ran particularly high in some quarters against what were considered disloyal and ungrateful former colonies. Notably those persons who had hitherto been strong imperialists and found difficulty in comprehending the concept of a free and equal Commonwealth association now spoke vehemently of abandoning both the remains of empire and the Commonwealth.

The British decision to seek a place in the European Economic Community was inspired in part by the impressive early success of that union and in part by the growing realization, emphasized at Suez, that perhaps Britain should seek its destiny outside its former Empire. On this occasion, however, Britain took pains to inform the rest of the Commonwealth of its plans. Britain had given advance warning of its intention to enter joint European activities by its participation as early as 1946 in the Anglo-French Economic Committee and in 1948 in the Organization for European Economic Cooperation. But never before had it been as clear that, faced with alternatives, Europe would come before the Commonwealth. In 1961 three senior British cabinet ministers visited Commonwealth capitals to explain their views, and while not encountering enthusiasm at the prospect of Britain's entry in the European community, they found at least a growing measure of resignation as to its inevitability. Gen. Charles de Gaulle's termination of the negotiations with Britain in 1963 did not destroy the apprehension which had been built up. Member states recognized now that Britain had opted for a future first within Europe and only second within the Commonwealth if this were also possible. The setback to Britain's plans in 1963 was seen as only a temporary rebuff. The probability had now to be faced by such close economic partners of Britain as New Zealand that at a not far distant date Britain might cease to extend preferences in trade and investments.

The decision by Britain in 1962 to restrict immigration from the Commonwealth, although dictated in part by special domestic considerations, was another significant manifestation of its changed attitude. The U.K. evidently no longer considered it worth substantial domestic sacrifice—in this case mounting population pressures, extreme housing shortage, and internal racial tensions—to preserve good relations with Commonwealth partners. The long-standing notion that citizens of Commonwealth countries had special status in other member states had been seriously strained by the emergence of republics within the association and by the replacement of the notion of British subject with specific nationality. With the Commonwealth Immigrants Act of 1962, it was dealt another serious blow.

The change in attitude of Britain toward its former empire was demonstrated in one more way during the 1960s by the almost unseemly haste with which certain dependencies were rushed into independence: Nigeria and Cyprus in 1960; Sierra Leone and Tanganyika in 1961; Jamaica, Trinidad and Tobago, and Uganda in 1962; Malaysia, Zanzibar, and Kenya in 1963; Malawi (Nyasa-

land) and Zambia (Northern Rhodesia) in 1964; the Gambia in 1965; Guyana (British Guiana), Botswana (Bechuanaland), Lesotho (Basutoland), and Barbados in 1966.

**13. Similarity Gives Way to Variety.**—Analyses of the Commonwealth in the 1920s and 1930s, and even as late as the 1950s, emphasized the unifying presence among the members of common political and social ideologies and institutions: parliamentary government with a cabinet system and opposing political parties; respect for the rule of law; sympathy for federal devices; military forces subservient to duly constituted authority; independent bureaucracy; economies of viable size; educational systems rooted in the British model; and even respect for the British crown. Progressively during the 1950s and 1960s many of these common elements began to disappear. Above all the British model of parliamentary government underwent steady and fundamental modification in many of the members. First, a succession of countries rejected the principle that the effective head of government should not also be the head of state; presidential government was introduced in Pakistan, Cyprus, Ghana, and Tanganyika. Second, in all the newer members the concept of a loyal parliamentary opposition expecting some day to assume office and meanwhile being tolerated by the party in power failed to take root. In some countries, political parties were formed strictly along ethnic, religious, or tribal lines, and acrimony among them made a friendly alternation of power inconceivable. Moreover, the general problem remained unsolved of how to finance and give permanence to opposition parties when the main financial returns from politics lay in the spoils of office.

The postwar phenomenon of massive international economic and technical assistance coupled with the partial redirection of cultural flows outside the Commonwealth contributed to a marked increase of diversity in the social institutions of Commonwealth countries. Technicians from the U.S., Western Europe, the U.S.S.R., and even Communist China flowed into the Commonwealth while at the same time students and professionals went to those countries. Old habits of purely British inspiration were broken while new techniques were learned and more complex links were established. For example, establishment of the University of Nigeria at Nsukka in 1955 with United States aid and on the pattern of an American land-grant college inevitably reduced the Nigerian dependence upon Britain in higher education which had been almost complete before World War II. Similarly, the training of military forces in Commonwealth African states by Scandinavian, Israeli, and Soviet advisers complicated the traditional dependence upon British military colleges.

But the most pronounced change in the pattern of Commonwealth social institutions began late in the 1950s with a movement toward various forms of authoritarian rule in the newer members, first in Ceylon in 1956, then in Pakistan in 1958, and to varying degrees during the 1960s in Ghana, Tanzania, Uganda, and Nigeria. In most instances the changes were claimed to be temporary and of an emergency nature. Nevertheless, their effect was to place in jeopardy the basis not only of political democracy in those countries, but of institutions such as the independent bureaucracy, the subservient military, and the federal division of power. For the first time Commonwealth meetings were attended by representatives of governments which had not been duly elected by the citizens of their countries. This change may be viewed as having demonstrated yet again the adaptability of the Commonwealth institutions. But it also may be seen as marking yet another decline in the meaning of the Commonwealth.

**14. Strains Within the Commonwealth.**—By the 1960s racial, religious, and ethnic tensions within and between member states came to be the greatest threat to the survival of the Commonwealth. Tensions of this type had a long history in Commonwealth countries and had contributed to the breakup of the Empire; racial conflict in Kenya and bitter enmity between Greek and Turkish communities in Cyprus helped to convince Britain of the increasing costs and decreasing returns in colonies. Most of the traditional strains of factionalism did not ease with independence, and a complex background of acrimonious internal and international disputes plagued the early years of many new nations. The

partition of India in 1947 was designed to resolve differences between Hindu and Muslim, yet by the mid-1960s animosities were strong enough still to bring India and Pakistan to open war over Kashmir.

The racial policies of South Africa brought increasing criticism from the new nations of Africa and Asia and finally caused that country to withdraw—in essence to be pushed—from the Commonwealth in 1961 when it applied for continued membership upon adopting a republican form of government. South Africa's departure brought a relaxation of some tensions within the Commonwealth, but also it left a legacy of suspicion and bitterness toward the association in the minds of many persons in the older member states. The South African racial policy of apartheid, more than any other single issue, galvanized opposition from the newer Commonwealth members. To the older nations, however, it was not always clear why internal oppressive racial policies of certain members should be condemned while political and other types of oppression in other members were ignored. The practice of conditioning membership upon majority approval of a member's internal policies, implicit in the expulsion of South Africa, was a significant and possibly fatal precedent for the Commonwealth.

Within several nations of the Commonwealth, tensions between powerful segments of the population were the most serious problems facing their governments. Singapore and Malaysia found the only solution to their differences in dissolution of federation. In Canada, after fully a century of nationhood, French and English Canadians still were locked in controversy over the meaning and future of their confederation. Most of the new nations of Africa seemed threatened by serious divisions along tribal lines. The only South American member, the new state of Guyana, began its existence in 1966 with a bitter heritage of racial turmoil. Even within Britain itself race prejudice became a significant political issue in the 1960s and affected its relations with some members of the Commonwealth.

Undoubtedly the most serious strain imposed on the Commonwealth by race conflict resulted from the dispute over how to deal with the rebellion against Britain in 1965 of the white settler minority in Southern Rhodesia. Legally, the issue was a bilateral one between Britain and an insubordinate territory. But in fact it was identified by the nonwhite Commonwealth as a test of Britain's good faith in its endorsement of racial equality and rejection of neocolonialism. The Rhodesian case raised strong feelings of ambivalence in parts of the old white Commonwealth. On the one hand, there was abhorrence of Rhodesia's policies of race inequality. On the other hand there was substantial uncertainty about the wisdom of demands for immediate independence with African-majority rule as voiced by the newer Commonwealth states. Disturbing political developments within some recently independent African states—ranging from anarchy in the Congo to dictatorship in Ghana—fed this uncertainty. There was also evident horror at the possibility of armed intervention to achieve a settlement in Rhodesia. Although differences of view over the correct policy for Britain to pursue toward Rhodesia did threaten the survival of the Commonwealth, in one way the crisis demonstrated the potential usefulness of the association. The meetings of Commonwealth prime ministers at Lagos in January 1966 and in London in September at least helped to avoid open conflict and succeeded in obtaining agreement for a time on approaches to the problem.

**15. New Focus and New Institutions.**—In the 1960s it was evident that the Commonwealth was still an evolving entity with two functions becoming more important than all others. First, the Commonwealth provided a useful centre of contact for members. It did not duplicate the United Nations, supplant military defense agreements, or compete with regional economic pacts; but in a world where international conflict was an ever-present menace, it made available to nations a relatively friendly forum for debate and flexible opportunities for consultation on matters specific or general. The second main function of the Commonwealth was to provide cooperative approaches to problems of modernization in the newer members. Although the older Commonwealth members may have regarded the first function as more important, the second

was recognized and emphasized by the Asian and African members. In magnitude, Commonwealth assistance was often overshadowed by bilateral aid from non-Commonwealth sources. Nevertheless, the economically less developed members saw the Commonwealth as a significant channel for the inflow of capital and trained personnel. Without an organization such as the Commonwealth, it was feared that the old dominions and even Great Britain, relieved of its imperial responsibilities, might reduce their commitments abroad. Faith in the Commonwealth as a mechanism of economic assistance was confirmed by a steady stream of aid from Britain to its former colonies and from Canada and Australia to the Commonwealth in greater proportion than to the rest of the world.

Formal recognition of the two dominant roles for the Commonwealth came with establishment of the first pieces of institutional machinery for the association in 1965: a secretariat and a Commonwealth Foundation to administer a fund for increasing interchanges between Commonwealth organizations in professional fields throughout the Commonwealth. In essence the secretariat was designed to facilitate consultation and the foundation to increase assistance and exchange (*see below, Cooperation and Consultation*). These institutions were established to help the Commonwealth do what it had always done before but with a more international base and with the recognition that Britain was more nearly an equal partner than a dominant force. So long as vestiges of the imperial tradition had remained in the Commonwealth, an organizational structure had been vigorously opposed on the ground that it might lead to control, and by no country more vociferously than by Canada. Now, after the interest of the mother country in colonial possessions had demonstrably waned and apparent real value in the Commonwealth remained, some members, notably Canada and the new African states, sought to infuse new life and activity into it. Establishment of an institutional structure for the Commonwealth in place of the old informality of relations based on British dominance was continued evidence of two postwar developments: rapid evolution of the Commonwealth to take account of changing world conditions, and a movement to genuine equality among Commonwealth members. The more formal structure could be viewed as a potential source of strength to the Commonwealth by increasing the benefits to members of the relationship. It could be seen also as a potential danger in that it might lead to abortive attempts at formulation of a common foreign policy and to exertion of excessive pressure upon members for alteration of their internal policies.

The Commonwealth in the 1960s faced internal and external strains which threatened its survival. It also continued to have significant political and economic functions, a remarkable capacity for adjustment to change, and an extraordinary ability to survive which confounded its critics. (C. D. W. G.)

#### IV. COOPERATION AND CONSULTATION

In this section the working of the contemporary Commonwealth is considered first in terms of the distinctive institutions which it has developed: the Commonwealth secretariat; the meetings of prime ministers and other heads of governments; the diplomatic consultations; and the special character of high commissioners. Attention is then drawn to the forms taken by economic, defense, scientific, educational, and legal cooperation among Commonwealth members. Following a brief discussion of nationality and citizenship arrangements as these affect Commonwealth states, there is a description of the organizations which operate on a Commonwealth level, some being official and others private in character.

The various institutions considered here do not form part of a coherent system laid down by any central Commonwealth authority. Some, such as the Commonwealth secretariat and the bodies implementing the decisions of the Commonwealth Education conferences, have been authorized by the meetings of prime ministers. Others have grown in accordance with needs and have carried on their work without this kind of central sanction.

**1. Commonwealth Secretariat.**—For many years there was no central office for the Commonwealth. This was usually considered a reflection of the looseness of Commonwealth arrangements, and of the complete independence enjoyed by members.

In 1964, however, under some pressure from African members but with the support of Britain, the Commonwealth prime ministers decided to institute a Commonwealth secretariat, at the head of which would be a secretary-general. In 1965 the proposal was put into effect, the first secretary-general being Arnold Smith, Canadian diplomat. He and his staff were housed in London. They were not given any direct authority. Their tasks were to ensure the dissemination of factual information between member governments, to assist existing agencies to promote Commonwealth links in various fields, and to make preparations for meetings of prime ministers and other ministers, in cooperation with whichever country was host on the particular occasion. The secretariat's staff was recruited from a wide range of Commonwealth members.

It became clear that, when a secretariat was being discussed, some Commonwealth members wished it to have more influence than others. Some governments were said to envisage the secretary-general's function as akin to that of his counterpart in the UN; he was to have a certain independence of jurisdiction, with the possibility of introducing matters of importance into Commonwealth discussions even if they were not suggested by particular members. Other governments thought this would constitute interference in the affairs of members. They wished to continue the existing convention that only those matters were discussed to which no member objected. The upshot was that the secretariat was given compromise powers, a little wider than those of a post office but hardly independent or even executive in character. During its initial period, the secretariat's energies were directed mainly toward organizing conferences of prime and other ministers (this had previously been undertaken by agencies of the British government, since most of the conferences were held in London) and attempting to coordinate the affairs of the other Commonwealth bodies. The secretary-general spent some time in serving as a link between the older Commonwealth members and the newer ones from Africa, the governments of which were, at the time of his appointment, disturbed about the direction and possible consequences of British policy toward Rhodesia.

Whenever the heads of governments in the Commonwealth can be persuaded to engage in common action, the secretariat was to be available to interpret their views to one another, and to ease the problems of administration. It was unlikely to develop as a source of Commonwealth policy. Its value would probably lie in the additions which it could make to the system of contact between Commonwealth states described immediately below.

**2. Commonwealth Meetings.**—The business of general Commonwealth discussion is largely carried on at meetings of ministers from the member states. The most important are meetings of prime ministers, but those among finance and trade ministers are also significant.

Meetings of Commonwealth prime ministers are in direct line of descent from the imperial conferences which took place between 1907 and 1937. There was no return to the term "imperial" after World War II. Meetings of prime ministers took place frequently after 1944, much more often than did the imperial conferences. Apart from the difference in title, there have been certain differences in style. The imperial conference operated against a background of assumptions which included a common crown and a common foreign policy for the Commonwealth as a whole. It was expected that decisions would be announced as the declared policy of the empire, which at that time was assumed to include the British Commonwealth within it. In spite of hesitations and occasional opposition from governments in Canada, South Africa, and the Irish Free State, those were the broad assumptions in the 1920s and 1930s. Since World War II, there has been no attempt to sustain them. It has been recognized that each member is free to pursue whatever policy and extra-Commonwealth associations it wishes. The effect on the meetings of prime ministers has been to make them less formal than were the imperial conferences, with more discussion but fewer decisions.

The decisions made by prime ministers (including also presidents, where those are heads of government as well as heads of state of their respective countries) are mostly concerned with questions of membership and procedure. They rarely express

agreement on foreign policy. The communiqué which results from a meeting is normally confined to a brief statement of the subjects discussed, and a summary of the opinions expressed, often without naming the countries which expressed them. At times contentious issues have made it necessary to indicate sharp differences of opinion. But the main aim of the prime ministers seems to have been to avoid open controversy and to respect the wish of any member to withdraw a particular topic from discussion. Thus, although the Kashmir issue has been a matter of deep dispute between two Commonwealth members since 1947, the prime ministers have not attempted to pass judgment on it but have confined themselves to efforts at conciliation outside the formal meetings. The increase in the number of African members has led to a sharper edge to controversy over African questions.

The prime ministers' meetings have gone through two broad phases since the end of World War II. In the first, which lasted until 1956, the membership was small, the discussions were largely concerned with the reshaping of the world after the war, and international economic questions (especially the operation of the sterling area) took up much time. In the second phase, the emphasis has been largely upon certain colonial issues, and upon the problems of former dependent territories, especially in Africa, in their effort to improve their economic position by means of technical assistance and capital aid. In each period the leadership of the meetings rested largely with Britain. The British government arranged meetings in accordance with the wishes and convenience of the other members, and was largely responsible for the agenda, and the British prime minister normally served as chairman. In 1966, however, the change of tone resulting from an increased African membership was signaled by a prime ministers' meeting at Lagos, Nigeria, at which the chair was taken by the prime minister of Nigeria. This was the first such meeting to be held outside Britain. It was specifically concerned with British policy on Rhodesia. Australia refused to be represented on the ground that Rhodesia was essentially a British domestic concern and that it was not the function of the Commonwealth prime ministers to put a member in the dock. The British government attended the meeting, and agreed to the setting up of a continuing committee of Commonwealth representatives to which it would report progress on Rhodesia, presumably because it preferred to deal with the objections of the African members in a Commonwealth context, rather than solely within the UN.

Certain formal rules of procedure have developed for the prime ministers' meetings, although the keynote is flexibility. The most important is that a Commonwealth member which intends to move from the status of a monarchy to that of a republic must ask the other members for approval of its continued Commonwealth membership. This is something of a historical anachronism. It arose from the request of India in 1949 to remain in the Commonwealth while becoming a republic. Logically, there was no need for the point to be made more than once, but the custom has been for members to make the request and to have it granted automatically. The only exception was that of South Africa, which found that other members wished the matter to be fully discussed, because of what they regarded as the unsatisfactory character of South African racial policy. It was customary to claim the "multi-racial" character of the Commonwealth as one of its best characteristics; South Africa, it was said, violated this aspect of Commonwealth practice. After South Africa left the Commonwealth, multiracialism was adopted as one of the requirements in any country seeking membership, but was stated in terms sufficiently ambiguous to cover the practices of the existing members.

A meeting of prime ministers may be regarded as analogous to those visits of heads of governments to one another which have been so prominent a feature of international relations since World War II. It acquires extra importance from being one of a continuing series and from including so many countries. No other series of international gatherings, even at the UN, brings together so regularly so many heads of governments. It is a form of continuing consultation, providing an extra dimension for the strategies which the member states pursue in their external relations.

Other meetings between Commonwealth ministers have gen-

erally received less publicity but occur often enough to warrant attention. The most frequent are those involving finance ministers. Before 1958 these took place at such times as the conditions of world trade and the circumstances of sterling seemed to demand. In that year a large-scale Commonwealth Trade and Economic Conference at Montreal established a Commonwealth Economic Consultative Council, consisting of the finance ministers of the member countries. The ministers were to meet yearly; their officials consult regularly in London between these meetings. No formal power is vested in the finance ministers as a group, but their meetings enable the member states to convey the policies of their governments to other members. Similarly, occasional meetings of trade ministers enable members to voice forcefully the needs which they hope common action will satisfy. Sometimes the point of such meetings may be pressure from the other members on Britain, as when they stated in 1961 at Accra the unfortunate results which they expected would follow Britain's entry into the European Economic Community. At other times all members have found common cause in the desirability of a lowering of U.S. tariffs; in such a case their conclusions have been carried over into other non-Commonwealth meetings at which a joint Commonwealth standpoint could be expressed. Meetings of finance and economic ministers do not work out a system of economic control for the whole Commonwealth, but they often enable members to deploy their individual strategies in international economic matters and to develop a unified strategy when feasible.

**3. Additional Consultative Devices.**—For a considerable period the hub of the Commonwealth system was the Commonwealth Relations Office, a ministerial department of the British government. The history of this department parallels the evolution of the Commonwealth. The traditional department for imperial questions, except those relating to India, was the Colonial Office. In 1907, at the prompting of the self-governing dominions, a dominions section was set up within it. In 1925 this became a separate department of state under the name of the Dominions Office. The name was changed to Commonwealth Relations Office (CRO) in 1947, following the independence of India and Pakistan. The former India Office was merged with the CRO. The Colonial Office (CO) continued to be responsible for all non-self-governing territories except Southern Rhodesia and the "High Commission territories," which were administered through the CRO, the first because of its internal self-government, and the latter because of their close connection with South Africa, which was a Commonwealth member. In the main the CRO's task was essentially diplomatic. It performed for Commonwealth members the work which the Foreign Office did in the case of foreign countries. Its staff manned the high commissions in Commonwealth countries and its ministerial head, the secretary of state for commonwealth relations, was a member of the Cabinet and responsible for communicating Commonwealth reactions to it. The location of the CRO and the Foreign Office in the same building in London ensured some coordination of British external policy.

As more British dependencies became independent, the work of the CO shrank while that of the CRO expanded. When a territory's relations with Britain were transferred from the CO to the CRO, this was an indication that it had gained full independence: the former department was concerned with rule, the latter with the normal relations of one sovereign state with another. Following numerous suggestions for a merger of the CO and CRO, or of the CRO with the Foreign Office, the Plowden Committee reported that the services of the Foreign Office and CRO should be brought together in a unified Diplomatic Service, but that separate offices should be maintained in order to emphasize the importance to Britain of Commonwealth connections. Following this change, it was decided that the CO should cease to exist as a separate department. In 1966 it and the CRO were formally merged into a new Commonwealth Office, at the head of which was the former secretary of state for Commonwealth relations, now entitled commonwealth affairs. An assistant minister remained responsible for the Dependent Territories Division, which did the work of the former CO. Thus, the Commonwealth Office, having grown out of the Colonial Office, eventually swallowed its parent.

No other Commonwealth member has separate departments for the handling of Commonwealth and foreign affairs. Many have Commonwealth divisions within their departments of external affairs. No other has attempted to retain a separate diplomatic service for Commonwealth posts, as Britain did until the 1960s. These differences show the major importance of the Commonwealth to Britain, as compared with its importance to other Commonwealth states. Successive British governments have wished to emphasize the difference between those countries which were regarded as in a sense part of an extended British family, and those which were foreign. The difference was emphasized by giving Commonwealth residents immediate citizenship on their arrival in Britain and by exempting them from the rules applying to aliens.

The special character of Commonwealth relations, as distinct from ordinary foreign relations, may not be apparent to all Commonwealth citizens, but it is kept alive by certain practices involving ceremony and consultation. The Commonwealth diplomatic representatives in a foreign country visited by the British monarch are, as a group, given special precedence in ceremonies, whether their countries are realms or republics, because the monarch is the head of the Commonwealth. It is customary for Commonwealth representatives at the UN to meet regularly for an exchange of views and to notify one another of the positions which they intend to take on particular issues. The Commonwealth Office regularly sends out to the external affairs departments of other Commonwealth states a great quantity of information about British policies and world affairs. For those Commonwealth members which have large diplomatic networks of their own, this information is valuable for the light which it throws on British official intentions. For smaller and newer members, which may have only a rudimentary diplomatic service in a few places, the information also provides insights into other developments in world affairs.

The business of consultation is not so smooth as many descriptions of it might suggest. The British government has been anxious that Commonwealth countries should know, and if possible sympathize with, the policies that it intended to follow. On their part, other Commonwealth countries generally have wished to accommodate their policies with Britain's if this did not cause difficulties for them. For all, including Britain, are sovereign states with interests of their own to pursue; at times they find themselves on opposite sides on a particular issue. The business of communication can hardly be expected to include an obligation to reveal all aspects of policy to a possibly hostile state. Accordingly, Commonwealth members tell one another what they think they ought to hear. At times, of which the most notable was the British shutdown of information over the Suez crisis of 1956, the flow of communication may cease.

Nevertheless, Commonwealth countries have usually wished to see it continue. Moreover, consultation may occur without recourse to formal notes or telegrams, and may consist simply of conversations at the right time and place. In this regard, the universality of the English language among the officials of all Commonwealth members makes communication easy.

**4. High Commissioners.**—A special mark of Commonwealth diplomacy is that the envoys accredited from one Commonwealth state to another are called high commissioners, although they have the status of ambassadors. The term, originally applied to an individual on special royal service of some kind, was used to describe the first Canadian representative to the United Kingdom, and was later used by other dominions. Britain did not begin to appoint high commissioners to other Commonwealth countries until 1928, after the Imperial Conference of 1926 had decided that governors-general, who had been regarded as representative of the British government, should in future be subject to the advice of the local government and not be formally connected with Britain.

The differences between high commissioners and ambassadors go beyond the difference in name, although their formal status is the same. It is customary for a high commissioner to have direct access to the prime minister of the Commonwealth state to which he is accredited, and not to be confined, as an ambassador is, to the right of access to a minister for external affairs. By having this privilege a high commissioner can act as a direct representa-

tive of his own prime minister. Prime ministers' departments may, in some cases, have special functions in regard to Commonwealth relations which they do not exercise in other spheres of external affairs. It is customary, not exceptional, for Commonwealth prime ministers to communicate directly with one another in the periods between prime ministers' meetings; this is one of the ways in which Commonwealth relations may acquire a special quality less often found in relations with non-Commonwealth states. However, practice varies from nation to nation. If Commonwealth members diverge sharply on policy, consultation will not necessarily bring them closer together; but if they are sympathetic toward one another, the system will ease their discussions at many points.

Each of the overseas Commonwealth states has maintained a large High Commission staff in London, usually headed by a political appointee who acts as the personal representative of his prime minister or president. There are also advisers on trade, finance, labour, defense, and contracts. In some cases officers attend to the needs of students in Britain; in others there are staffs dealing with migrants to their countries from Britain. High commissioners and their chief officers have special access to British government departments and need not route their inquiries through the Commonwealth Office. In other capitals of the Commonwealth, staffs are usually much smaller and vary with the closeness of relations between the countries in question; not all member states are represented in one another's capitals by high commissioners.

The High Commission system represents a variation from normal diplomatic relations. It is meant to make Commonwealth relations more familiar than those between foreign states. In this it obviously owes much to the earlier period, before 1947, when there was still a considerable ethnic connection between Britain and the dominions, and the "family" conception accorded more with the facts than it does now. However, the newer members have shown considerable readiness to adapt the system to their own ends. In most cases Britain is the principal element in their external relations, because of the economic, cultural, and other ties which remain from the colonial period. They have welcomed the opportunity to take advantage of a special relationship. But the same degree of intimacy has not prevailed between them and other Commonwealth states, largely because of remoteness, strangeness, and lack of interests to bind them together. The flow of communication is largely to and from London; there is comparatively little between Accra and Wellington, or Kampala and Karachi, unless some unusual event calls for it.

**5. Economic Cooperation.**—It is often stated that a degree of harmony in economic interests has been the main reason for the continued existence of the Commonwealth since World War II. The elements of this cooperation can be seen in the sterling area, in trade, in investment, in development programs, and in communications. These are considered in turn below. First, however, it is important to recognize the historical basis on which Commonwealth economic cooperation rests.

Each Commonwealth country outside Britain differs from the others in its geographical position, its natural endowment, its capacity to produce, its share of world trade, its standard of living, its degree of economic control, and its prospects for growth. Broadly speaking, those which have been subject to European settlement—Canada, Australia, New Zealand—have modern, highly developed economies, with substantial domestic and external investment and with highly sophisticated systems of production in both rural and urban industries. The remaining countries vary considerably in modernization and in their standards of living, but can all be classed as underdeveloped, with great improvements to be made in education, health, housing, and other social services; with comparatively little industrialization; and with only a few products, mostly basic commodities, entering into world trade.

The element binding together these differing economies is the impact on them of Britain, expressed in monetary arrangements, trade, investment, and in the diffuse influence of such things as language, weights and measures, forms of technical training, and cultivation of similar consumer tastes. This impact has necessarily been heavier and more uniform in the countries of settlement than in those which were simply subject to British adminis-

tration. But the extent to which modernization has become an attribute of Commonwealth states' economies has been largely due to British influence, especially in trade, and has often been aided by British capital investment. This state of affairs was especially characteristic of World Wars I and II, particularly World War II, in which Britain had to rely upon what are now Commonwealth members for a large proportion of its supplies.

**Cooperation in the Sterling Area.**—The sterling area is a product of the circumstances just described. Before World War II, there was no formal organization of the countries which tied the value of their currencies to sterling and which kept their international balances in London; but it had become apparent in the depression of the early 1930s that there was a natural tendency for countries which traded heavily with Britain, and which had been linked with the British money market through investment and the financing of their trade, to keep their currencies in line with sterling. Some of these countries were inside the Commonwealth, some were outside. On the outbreak of war in 1939 the association since known as the sterling area was designated by the British government. Its features, during the war and for some years afterward, were as follows: the members were those countries which held their international reserves in sterling; these agreed to maintain common standards of exchange control; there was constant communication between the Bank of England and the central banks of the other countries concerned; transfer of funds from Britain to the other sterling countries was on a more liberal basis than to countries outside the area. The countries concerned were mostly those of the Commonwealth (not including Canada); the foreign countries included were small and under British influence. In effect, the sterling area was the Commonwealth at war, with funds moving fairly easily within it, but with a united attempt to conserve foreign currencies earned by the members, especially dollars, in order to buy essential supplies.

The monetary situation thus established was reinforced by the practical operations of the war itself. Britain bought even more from Commonwealth countries than before, often under formal bulk purchase agreements. It was not possible either to pay for these with goods, or to pay for them in convertible currency. Instead, the supplying countries, such as Australia and Nigeria, built up large sterling balances in London, to be drawn upon when the war was over. Similarly, the cost of British troops in countries like Egypt and India was credited to balances in the names of those countries (see also *Development of the Sterling Area*, above).

The income from British investment abroad had, meanwhile, been sharply reduced; such international services as shipping had not been restored to peacetime earning power; and British civil exports were only beginning to appear again. Because of the critical situation, the arrangements of the sterling area continued in force in order to conserve gold and dollars. A premature attempt at general convertibility failed in 1947; the pound sterling was devalued in 1949. Commonwealth countries continued to support the British government and to hold their reserves in sterling. It was not until 1958 that sterling was made officially convertible, for non-residents, into any currency. But, in the meantime, it had been freely available to Commonwealth members to finance their trade, and the British government had permitted free transfer of capital investment funds to the Commonwealth, while keeping a strict control over investment elsewhere. Even after sterling became convertible, Britain retained restrictions upon investment in foreign countries, while permitting it freely in the Commonwealth. Only in 1966 were informal curbs placed upon Commonwealth investment in an attempt to improve the British balance of payments and increase investment at home.

The operation of the sterling area has been of considerable advantage to overseas Commonwealth countries. Apart from the benefits of a large trading area in which goods could move freely, they suffered no reduction of their wartime sterling balances in spite of U.S. urging that these should be scaled down; they benefited from one another's dollar earnings when they had sterling surpluses but were in dollar deficit; they were given special opportunities to sell in the British market because of restrictions on purchases which had to be paid for in dollars; and they had

free access to the London money market. Furthermore, Commonwealth countries were directly concerned in the functioning of the sterling area's machinery. The British government constantly consulted the other governments about the broad lines of trade and financial policy, and the Bank of England remained in constant touch with individual central banks. After 1958, the joint advantages of the sterling area became fewer. Trading opportunities broadened considerably with the reentry of Japan and the major European countries into world trade. The United States made more dollars available through aid programs. U.S. lending increased. Britain thus became less of a magnet for its Commonwealth associates, both as a market and as a source of funds. From a British standpoint, similar changes took place: the other Commonwealth countries were not such dependable markets as they had been (often on account of their protective policies); they were often less attractive as investment prospects than European or U.S. possibilities; and the continuance of some of their sterling balances at high levels posed something of a threat to the meagre British gold and dollar reserves. However, although restrictions were relaxed and Commonwealth economic connections grew looser, there was still sufficient appreciation of sterling's value as a world currency to keep the currencies of the sterling area's members tied to it and to preserve the framework of the area's machinery in case of future difficulties.

*Commonwealth Trade.*—Commonwealth trade is difficult to put into perspective, because of its highly diverse character. Two points of background are important. One is that Britain did not attempt, during the 19th and 20th centuries, to confine its colonies' trade to itself, but pursued an "open door" policy which enabled the colonies to find markets wherever they might exist. The other is that the self-governing colonies (dominions from 1907) persistently, throughout the early part of the 20th century, tried to persuade the British government to institute preferences in trade whereby the products of those countries (especially temperate climate foodstuffs) would enjoy advantages over imports from Europe and such competitors as Argentina. The British government resisted these efforts until 1919, when it made some move toward satisfying the dominions' wishes; but it did not institute anything approaching a comprehensive preference system until 1932, when, at the Ottawa Conference, agreements were made between Britain and the individual dominions, between one dominion and another, and with Britain on behalf of certain colonies. These did not cover the whole range of Commonwealth trade, but did provide reciprocal advantages in Britain for the preferences which the dominions had long provided in their markets.

The preference system was never fully revised, although subsequent agreements were made by Britain with certain Commonwealth countries to bring particular aspects of it up to date. There have also been agreements to provide special advantages in the British market for such Commonwealth products as sugar, meat, butter, and wheat. The failure to move on to any substantial agreement on intra-Commonwealth trade may be attributed to several factors: the fact that the Ottawa system, instituted to meet the ills of a depression, did not meet the needs of more buoyant times; the determination of the overseas countries to encourage their own manufactures at the expense of British imports; the opposition of the U.S. to preference systems as such; the difficulties of accommodating further preferences to the Commonwealth states' obligations under the General Agreement on Tariffs and Trade (GATT); and the persistence of free trade sentiment in Britain, coupled with a wish to negotiate better trade conditions with European countries.

Commonwealth trade in the mid-1960s thus involved the remnants of a preference system which did not apply to all countries equally (many of the newer Commonwealth members had little or nothing to do with it, since they kept to free trade arrangements when colonies in 1932), and which has been overtaken by new conditions. It also involved for some years the remnants of special wartime commodity agreements. These, together with the restrictions on trade with dollar countries in the 1940s and 1950s, helped to perpetuate a situation in which much of Britain's trade was with Commonwealth countries, and vice versa. Yet in the 1950s

intra-Commonwealth trade began to decline, and in the 1960s new pressures began to show their influence; the proportions of Commonwealth trade declined in all cases, even where, as in New Zealand and Australia, trade with Britain had been of paramount importance. (See above, *Currency, Trade, Investment, Migration, and Economic Growth*.)

Such an increasing diversification of trade was one of the reasons why the British government decided to apply for membership of the European Economic Community (EEC) in 1961. During the negotiations in Brussels it tried to ensure that the essential interests of other Commonwealth countries were safeguarded, although Commonwealth preferences in Britain against the EEC would inevitably decline and eventually disappear. Several Commonwealth members maintained their own representation in Brussels during the negotiations. When these broke down in January 1963, substantial agreement had been reached about manufactured goods from India and Pakistan, and about the possibility that tropical countries in the Commonwealth might become associates of the EEC. There was still no agreement about temperate foodstuffs from Canada, Australia, and New Zealand, although it had been recognized that New Zealand constituted a special case because of its heavy dependence on the export of meat and dairy products to Britain. In subsequent years certain Commonwealth countries continued to negotiate with the EEC. Nigeria secured associate status in 1966, by which time it was generally agreed that, if Britain applied again for admission, the remaining Commonwealth problems would be fewer and would be largely centred on New Zealand.

*Investment.*—Broadly speaking, British investment in the Commonwealth has been heaviest in those countries with which British trade has been greatest. All members have benefited from British investment, but the heaviest concentrations have been in Canada and Australia. In the early 1960s between £100,000,000 and £150,000,000 annually was being invested by British firms in Commonwealth countries; firms in the overseas Commonwealth were borrowing at least £40,000,000 annually on the London money market, and public authorities in Commonwealth countries were also borrowing at least £10,000,000 annually. These sums supplemented a massive total of former investments, which made Britain the principal source of existing "foreign" capital in all Commonwealth countries except Canada. During this period the members of the Commonwealth also borrowed from other sources, including the World Bank, and there was a considerable increase in U.S. and other foreign investment in their economies; but Britain was still their principal source of supply. The flow of British capital was likely to be affected, however, by a greater concentration on domestic investment and by increasing British investment in continental Europe. (See also above, *Currency, Trade, Investment, Migration, and Economic Growth*.)

*Development Programs.*—Commonwealth development programs increased in importance as more countries gained their independence. Britain made special arrangements to assist Commonwealth members. These took the form of Commonwealth Assistance Loans for the purchase of goods and services from Britain; Colonial Development and Welfare Assistance grants and Exchequer loans for dependent territories; the resources of the Commonwealth Development Corporation, a body authorized to borrow up to £130,000,000 from the Treasury to carry out projects for developing resources in former dependencies on a commercial basis; the Commonwealth Development Finance Company, which invests in development projects on an authorized capital of £30,000,000, raised from private firms and central banks; and contributions to the World Bank for loans expressly to Commonwealth countries.

In addition, Britain contributed with other developed Commonwealth members to the Special Commonwealth African Assistance Plan, an attempt to coordinate financial and technical aid to Commonwealth African countries, and to the Colombo Plan, which was a scheme, drawn up at a meeting of Commonwealth Foreign Ministers at Colombo in 1950, for technical assistance and capital aid in Asia. It was originally confined to Commonwealth countries as donors and recipients, but was widened to include the U.S.

and Japan as donors and a number of non-Commonwealth Asian countries as recipients. However, Commonwealth participation remained strong. Britain contributed about £280,000,000 in capital aid between 1951 and 1964, nearly all of which went to India, Pakistan, Ceylon, and Malaysia. During the same period Australia contributed approximately £A38,000,000 in capital aid and £A15,000,000 in technical assistance, about half of which went to Commonwealth countries. Canada contributed about Can\$450,000,000 in capital aid, nearly all of which went to Commonwealth recipients. The same was true of New Zealand's contributions.

**Communications.**—There were numerous ways in which Commonwealth members cooperated with each other in economic terms, probably the most important being in communications. There was a Commonwealth Shipping Committee which considered the facilities for maritime transport on Commonwealth routes and inquired into complaints about freights and other aspects of shipping. Its activities reflected the fact that a great deal of Commonwealth freight and passenger traffic was carried in British ships. There was considerable cooperation among the airlines of the Commonwealth countries, a number of which developed under the aegis of BOAC (British Overseas Airways Corporation). On round-the-world flights, BOAC, QANTAS (Australia's overseas airline), and Air India had pooling arrangements; BOAC also had arrangements with Air Canada.

There has been a long tradition of Commonwealth cooperation in regard to telecommunications and postal matters. The former was demonstrated by the agreement of the Montreal Economic Conference in 1958 on the construction of a round-the-world coaxial telephone cable, work on which had gone steadily forward. There has also been a tradition of charging less for telegrams and postal articles within the Commonwealth than is charged in the case of foreign countries. The Commonwealth rate for press telegrams has had a considerable influence in preserving London as the source from which most Commonwealth newspapers outside Canada get their main overseas news. The national broadcasting undertakings of Commonwealth countries have all maintained close relations with the British Broadcasting Corporation.

**6. Defense.**—The Commonwealth is not an alliance, and its members do not agree on many issues of foreign policy. Two of them, India and Pakistan, have actually been at war with one another while remaining members; another, Tanzania, broke off diplomatic relations with Britain over Rhodesia but continued its membership. Nevertheless, there has been a considerable amount of defense cooperation within the Commonwealth. This has come about in several ways. These include formal treaties that have bound certain members. Britain and Canada both belonged to the North Atlantic Treaty Organization (NATO); Britain, Australia, New Zealand, and Pakistan were members of the Southeast Asia Treaty Organization (SEATO); and Britain had a defense agreement with Malaysia and bases in Singapore, both of which arrangements were supported in practical terms by Australia and New Zealand. The British, Australian, and New Zealand troops located in Malaysia were called a Commonwealth Strategic Reserve. In the alliances which include non-Commonwealth countries, the Commonwealth element is not stressed.

Secondly, there were professional discussions, training arrangements, and strategic exercises, in all of which the main initiative was held by Britain, the country from which the other Commonwealth states have drawn their organization of defense matters and their standards of military excellence. There were annual conferences at which military service chiefs from Commonwealth countries were present. Commonwealth officers and civil servants regularly attended courses at the Imperial Defence College and the Joint Services Staff College in England; the Royal Air Force provided places for Commonwealth personnel as staff and students at its colleges. There was also some assistance to newer members from those outside Britain whose military organization was well established: Canada, in particular, was prominent in helping to train the officers of some of the African members. The main work in this field, however, was done by Britain.

Thirdly, there were arrangements concerning equipment and defense science. Britain traditionally provided most of the military

arms to other Commonwealth countries. There was considerable cooperation in the standardization of equipment and training, to make the supply process more efficient. Most Commonwealth navies were dependent on the Royal Navy, not only for their organization, but for the loan or sale of former ships and for subsequent advice on naval construction. A Commonwealth Advisory Committee on Defence Science kept Commonwealth countries abreast of the latest developments in this field.

It is noticeable that, even when there has been disagreement among Commonwealth members over broad issues of foreign policy (in particular, over the advisability of neutralism), defense cooperation has continued at the official and professional levels. The importance of this sort of contact has been emphasized with the growth of military regimes in certain Commonwealth countries. The prominent officers in the newer Commonwealth countries have had more to do with British habits and traditions in the military sphere than with the practices of British democracy.

Although, as already indicated, the Commonwealth is not an alliance and although there have been conflicts between some of its members, there is an undefined sense of responsibility in Britain toward Commonwealth members which might be menaced by foreign states. It has frequently been stated, and accepted, that Britain would help Australia and New Zealand if they were attacked, not because they are members with Britain of SEATO, but because they are Commonwealth countries to which Britain feels an obligation. The British government responded to requests for help from the governments of Kenya, Uganda, and Tanganyika in 1964 when these were threatened by local army mutinies; subsequently, special arrangements were made for British help with the organization of the armed forces in the first two. When India was attacked by China in 1962, the British, Australian, and New Zealand governments responded with arms and military equipment. It can be argued that these actions were dictated by broad considerations of British policy and were not primarily a matter of Commonwealth concern (Britain did not, for example, make any move against subsequent successful military revolts in Nigeria and Ghana). Australian and New Zealand support for Malaysia can also be regarded as stemming from general concern about Asia rather than from a direct Commonwealth interest. Nevertheless, it is likely that Britain and the other older Commonwealth states would rather defend Commonwealth members than foreign states, and would do so without the same need for a formal treaty.

**7. Education and Science.**—The great influence of Britain in training the principal educators and scientists of the Commonwealth is strikingly shown in the high degree of Commonwealth cooperation in education and science.

Apart from the Afrikaans- and French-speaking universities in South Africa and Canada, and the Royal University of Malta, the universities of the older Commonwealth countries all received their inspiration directly from Britain, especially in the manner of recruitment of teachers and in the subsequent influence of those men on professional standards and practices. The British government had little directly to do with the establishment of those universities; it was a matter of local initiative and of the enterprise of the staffs recruited. The Association of Commonwealth Universities (as it is now called) was first established in 1913 and has played a prominent part in the enlargement of the Commonwealth academic community. After World War II the British government directly encouraged the establishment of new universities in dependent territories. The universities which now exist in Ghana, Nigeria, Uganda, Kenya, Tanzania, Malaysia, Singapore, Sierra Leone, Rhodesia, and Jamaica were either begun in this period or developed from existing institutions with the active help of the British universities. The universities in India, Pakistan, and Ceylon had been established earlier, but have continued to participate with the newer universities and those of the older Commonwealth states in cooperative ventures.

The easy intercourse among Commonwealth universities had much to do with the first Commonwealth Educational Conference at Oxford in 1959. This conference laid down a plan for 1,000 university scholarships to be available throughout the Commonwealth at any one time, half being donated by Britain, a quarter by

Canada, and the remainder largely by India, Pakistan, Australia, and New Zealand. Stress was also laid upon teacher training and technical education, the older and more experienced Commonwealth states promising to provide special facilities for students from the underdeveloped members. There were further meetings at New Delhi in 1962 and Ottawa in 1964, each of which reviewed and extended the plans originally made. These did not represent a completely new departure: Canada, Australia, and New Zealand, as well as Britain, had provided many places for students from other Commonwealth countries before 1959. There was, however, more active and general consultation, supervised by administrative bodies set up in London.

No exactly comparable arrangements existed for science, although there was a Commonwealth Scientific Committee which consisted of the heads of the national research organizations of the Commonwealth countries and met yearly. There were also frequent conferences of scientists in particular fields (e.g., of nuclear scientists in 1958). Numerous contacts were also made between the scientific liaison officers at High Commission offices in London and official British agencies. The main force behind scientific cooperation, however, was the same as that behind educational cooperation: the fact that so many Commonwealth scientists, both in and out of government service, felt, because of their background, a sense of kinship with one another. It was often said that cooperation was likely to last longer in education and science than in other fields.

**8. Legal Cooperation.**—By definition, overseas Commonwealth members are free from the British legal system. Nevertheless, the impact of British law and legal practices was considerable upon all of them. British standards of legal ethics persisted. For example, one of the acts of former Pres. Kwame Nkrumah in Ghana which helped to bring about his fall was his dismissal of the chief justice because Nkrumah disapproved of a judgment he had made; the shock which this induced among people who had accepted many other divergences from British governmental norms was considerable. The freedom of the courts, and of the lawyers who practise in them, has been upheld throughout the Commonwealth. English common law has been a great bond, though it does not apply in all countries: in Quebec and Mauritius the basis of the law is French, and in Ceylon it is Roman Dutch. Legal precedent, including the decisions of English courts, carries weight throughout the Commonwealth. The organization of the legal profession everywhere bears evidence of English influence. These common factors help to explain two active aspects of legal cooperation: the continuing strength of the Judicial Committee of the Privy Council, and the Commonwealth Law Conferences.

The Judicial Committee of the Privy Council was set up to hear appeals from colonial courts on questions of law. It has no jurisdiction in Britain, although its members are mainly drawn from the British judiciary. Certain Commonwealth members have abolished the appeal, but others, including Australia, New Zealand, Ceylon, Malaysia, Nigeria, Sierra Leone, Jamaica, Trinidad and Tobago, and Uganda, have retained it. It is something of a tribute to a British court that newly independent countries should, in so many cases, have preferred to preserve it as a final court of appeal.

Commonwealth Law Conferences, which are assemblies of the legal profession in all Commonwealth countries, have been held in London in 1955, in Ottawa in 1960, and in Sydney in 1965.

**9. Nationality and Citizenship.**—Before 1946 the status of a British subject was the same throughout the Commonwealth and Empire, except for Ireland, although individual Commonwealth countries had laws which restricted the entry of British subjects from other parts of the Commonwealth as part of their general control of immigration. In 1946 the Canadian Parliament provided for Canadian citizenship while retaining for Canadian citizens the status of British subjects. A conference of experts from Commonwealth countries in 1947 decided, in effect, to recommend the application of the Canadian system to all parts of the Commonwealth. Broadly speaking, this has been done. Each member state has its own citizenship, that of Britain including the people of British dependencies. The status "British subject," or

"Commonwealth citizen" (the terms are for practical purposes interchangeable), is retained as a common attribute of all citizens of Commonwealth countries. It is, on the whole, easier for a citizen of one Commonwealth country to gain citizenship in another than for an alien.

None of the changes recommended since 1947 has, however, made it easier for Commonwealth citizens to claim unrestricted entry into other Commonwealth countries. Each is free to maintain whatever restrictions upon immigration it wishes. The last to institute stringent control over immigrants was Britain itself, which, up to 1962, permitted all Commonwealth citizens to enter as permanent residents without any of the restrictions imposed upon aliens. In that year, following public concern about a heavy flow of immigrants from India, Pakistan, and the West Indies, the British Parliament passed the Commonwealth Immigrants Act, which provided for control upon the numbers of Commonwealth citizens seeking entry, and for deportation where this was thought necessary. The act caused considerable controversy in Britain itself and was received coolly in some other Commonwealth countries, especially the West Indies; but its implications were no different from those of the immigration acts of other Commonwealth countries, although it was more specific in application. It applied, in any case, only to the actual entry into Britain and the length of stay. Once inside, all Commonwealth citizens immediately acquired all the same rights as their fellow British subjects.

**10. Organizations and Standing Committees.**—A number of bodies exist to foster Commonwealth links of different kinds. Some have already been mentioned (e.g., the Association of Commonwealth Universities, including approximately 130 universities and other institutions of higher learning). Other bodies of this kind include Commonwealth associations in various professional fields, and the Commonwealth Press Union. The Commonwealth Parliamentary Association forms a link between the members of the parliaments of Commonwealth countries. Like a number of other such organizations, it was started before the Commonwealth concept had been clarified, and the adjective describing it was changed from Empire to Commonwealth in 1948. With more than 80 branches throughout the legislatures of the Commonwealth, the association holds full conferences every one or two years, its expenses being met by grants from the various parliaments. The Royal Commonwealth Society, a cultural and social body which has no formal political connections, formerly dealt largely with the older Commonwealth countries but has widened its scope.

Certain other bodies have a more directly governmental role. These include the Commonwealth Agricultural Bureaus and the Commonwealth Scientific Committee, the Commonwealth Shipping Committee, and the Commonwealth Air Transport Council. The Commonwealth Education Liaison Committee and the Commonwealth Education Liaison Unit carry out tasks assigned by the Commonwealth Education Conferences (see *Education and Science*, above). The Commonwealth Economic Committee provides Commonwealth governments with economic and statistical services, largely in production and trade. The Commonwealth Telecommunications Board advises the governments and national telecommunications enterprises of the member states. The Commonwealth War Graves Commission maintains more than 1,000,000 graves from World Wars I and II. All these organizations are located in London.

**COMMUNE (MEDIEVAL)**. During the central and later period of the middle ages most of the towns of western Europe (i.e., to the west of the Baltic in the north and the Adriatic in the south) acquired municipal institutions which have been loosely designated as communal. A brief account is given here of these political and social institutions.

No definition embraces satisfactorily every type of commune, but most were characterized by the oath binding the citizens or burghers to mutual protection and assistance. Such an oath between equals, though analogous with other Germanic institutions, contrasts with the oath of vassalage typical of early medieval society, by which the man promised obedience to a superior in return for protection (see FEUDALISM). The body became an association, a *communitas* or *universitas*, capable of owning property and entering into agreements, of exercising varying degrees of jurisdiction over its members (who did not normally comprise the entire population of the town) and governmental powers. There were very marked regional differences between different types of commune. In northern and central Italy (and parts of southern France) the absence of powerful centralizing political authority

and, to a lesser extent, the precocious economic development of the towns enabled the commune to acquire a degree of self-government that easily surpassed the transaction of municipal affairs. Here the towns conquered the intervening countryside and pursued independent diplomatic policies, and their *de jure* superiors, the Holy Roman emperor or the pope, were rarely able to exercise *de facto* supremacy. The stronger of these city-republics survived—at the expense of their weaker neighbours—into the Renaissance, though by this time most had fallen to a single ruler (*signore*). Milan and Florence continued as powerful states into the early modern period and Venice right up to the Napoleonic era.

Nowhere else did the towns achieve such complete independence, but the communes of Flanders were in advance of all but the Italian in size and industrial and commercial organization, and at times political relations between the count of Flanders, the French king (his overlord) and England gave Ghent in particular an individual role on the European stage. In France, "Germany" (i.e., the imperial territories north of the Alps) and the Iberian kingdoms of Castile and Aragon, the towns were "judicial islands" having their own law and transacting their own business within the field of what would now be styled "local government." Here, as in the English borough (*q.v.*), the king or overlord normally retained supremacy but was willing to part with control in detail in return for financial benefits and military or other services. Obviously there are exceptions to these regional generalizations, for each town differed from all others in its social and economic development, its political history and its traditions.

The general importance in European history of the medieval commune lies perhaps in the social and political education acquired by the citizens through their exercise of self-government. It would be very wide of the mark, however, to imply that the communes were "democracies." The life of all the towns was characterized by a struggle for control, as a result of which the wealthiest and most powerful citizens (often called, by modern writers, patricians) were usually more or less successful in monopolizing power. Within the communes oligarchy was the norm. The direct inheritance of the modern nation-state from the communes was small, despite their role in parliamentary institutions, which was particularly important in the Spanish *Cortes* (*q.v.*). When monarchies were sufficiently powerful, they sought to stamp out municipal patriotism and civic organization.

Certain rural zones were also organized as communes, normally in response to the need for collective agrarian organization (pasturage and other rights or property held in common). There are important differences between such institutions and the urban communes with which this article is exclusively concerned, and which are treated here by geographic area.

## ITALY

In describing the communes of Italy one is concerned with the northern and central parts of the peninsula; i.e., with imperial territory and with the papal state. Certain communal institutions had developed in some of the cities of southern Italy and Sicily, e.g., at Naples, Amalfi and Messina, but these were stifled by the Norman rulers of the Sicilian kingdom in the late 11th and 12th centuries. Thenceforward, with the exception of a few brief and isolated episodes, the Normans and their Angevin and Aragonese successors prevented any development of municipal independence in the south comparable with that in the rest of Italy. This contrast is the clearest illustration of the fact that the cities of the centre and north owed their powers primarily to the nominal suzerainty of an emperor who was normally absent or of a pope whose temporal resources were feeble.

The origins of the Italian communes can be ascribed to no single cause, but the essential factors which made for their strength, apart from the lack of central control which marked the medieval period everywhere, were the survival of Mediterranean traditions of living together in urban communities and the big role of the Italian towns in the expansion of commercial and industrial activity which began in the 10th or 11th centuries and continued till the 14th. Though the continuity of civic institutions was broken, some of the Roman cities, aided by their walls and by the presence of a

bishop and ecclesiastical community, had survived as centres of population through the disturbed periods of Ostrogothic and Lombard settlement. Milan, for example, retained its importance as a road centre and the head of an influential bishopric, while Pavia became a Lombard capital and housed merchants, moneyers and other craftsmen connected with the court. Characteristic of the Italian town was the large proportion of the population engaged in agriculture who often traveled long distances daily to work in the fields. This was not merely a matter of tradition: the town, because of its walls, was a more secure place of residence, and it was often situated on high ground that was relatively healthy. Even more strikingly different from the towns north of the Alps was the presence within the walls of a number of nobles holding land in the countryside: a 13th-century Italian writer was to comment on the unconventional habits of the nobles of Bologna who lived outside the city in villas "like the French." The rank of these town-dwelling nobles varied, some being viscounts and captains, while others were mere knights, usually known as *valvassors*; some, too, lived permanently in the town, some for part of the year only. This minor rural aristocracy had benefited greatly by the breakup after the 9th century of the vast (mainly ecclesiastical) estates, and its members had often insinuated themselves successfully as *de facto* landowners between the lord and the cultivator of the soil.

If trade was not the main concern of the leading class in the early commune, it was nevertheless to give the towns their financial and demographic strength. In the period up to the 11th century, Italian maritime commerce had maintained a link with Byzantium and the eastern Mediterranean; this was the role of Venice and, to a lesser extent, of Bari, Naples, Amalfi and Gaeta. Venice was well suited to serve as an entrepôt joining the Mediterranean with northern Europe, while Milan was the base south of the Alps of the communications extending into France. The 11th century saw a great expansion in trade in the Tyrrhenian sea and, in particular, the rise of Genoa and Pisa. Even before the first crusade (1096-97) these cities had raised naval expeditions to harry the Muslims in Sicily and north Africa. After an initial period of caution, the three great maritime towns gave their assistance to the crusaders and were rewarded by the grant of trading "colonies" (privileged quarters) in the towns of the Syrian littoral. These ports of the crusading kingdom of Jerusalem thus became the main places of transit during the great period of expansion of trade between western Europe and the east, though there was also considerable commerce with Constantinople and often with Muslim towns, such as Alexandria. The crusading movement was thus not so much the cause of increased commercial activity as the means that determined its routes and institutions. By the 12th century there were considerable communities of merchants and financiers in a number of inland cities, such as Cremona and Piacenza in Lombardy, Padua and Verona in Venetia, and Florence, Lucca and Siena in Tuscany. Some towns (Piacenza and Siena) specialized in banking, while most developed industry and crafts producing for a fairly localized market.

**The Boni Homines, the Consulate and the Arengo.**—The towns in which the merchant class was sufficiently powerful to play an important part in the early history of the commune were, however, exceptional. The dominant class in the 11th and 12th centuries was normally the landowning nobility, whose juridical superiority as experts on local custom and as the normal arbitrators and legal witnesses was recognized by their denomination as *boni homines* ("good men"). The crucial stage in the formation of the commune came with the desire to formalize the transaction of common municipal affairs by the *boni homines*. The need to maintain local defenses (in particular the walls) and to regulate weights and measures and other matters pertaining to markets and fairs, as well as mutual religious activities, must normally all have played a part in shaping municipal co-operation. Such matters could not be left entirely to the bishop, who was often the *de facto* (though more rarely the *de jure*) local representative of the emperor's power. At Milan and certain other towns religious disputes with the bishop did much to crystallize the nascent commune, and as the community gained in strength and confidence, it tended to take over some of the functions hitherto exercised by the bishop. Thus

neighbouring towns which became subordinate often submitted at the earliest communal period to the recognized authority of the bishop, later to the bishop and commune and, finally, to representatives of the commune alone.

References to the "formation" of a commune are rare in contemporary sources: the process was a gradual one and tended to go unnoticed. The leading inhabitants of a town normally collaborated and acquired certain virtually governmental rights some time before they possessed communal institutions and officers. At Milan the *valvassors* revolted against the archbishop in 1035-36 but there is no surviving reference to consuls before 1097. Florence had its own weights and measures in 1079, embarked on the conquest of the surrounding countryside in 1107 but is not known to have had consuls before 1138. The appointment of a definite executive, the consulate, was thus a further stage in the formalization of an increasingly busy institution. The title consul shows the Italian lawyers' awareness of the Roman past. Most of the larger towns were coming to possess the consulate by the end of the 12th century; e.g., Pisa c. 1084, Asti in 1093, Arezzo in 1098, Bologna in 1123, Siena in 1125 (these earliest references, however, are compatible with the existence of the institution some time before). The number of consuls varied in the different towns and from time to time. Milan had 18 (most of whom were nobles) in 1117, at least 23 in 1130, 4 in 1138, 8 in 1140, 6 in 1141. By the second half of the 12th century consuls with judicial functions (*consules causarum* or *pro placitis*) were often differentiated from those with executive duties.

In this stage of its formation the most characteristic institution of the commune was perhaps the parliament of all the citizens, the *arengo*, rather than the consulate. It was only slowly that the right of representatives (or even of a majority) to bind the commune by their decisions was recognized and that the transaction of business by a large gathering was abandoned as impracticable. The status of the *arengo* was in part the result of the private and even temporary nature of the commune in its earliest manifestations. The Genoese commune or *compagna* was in 1157 still formed for four years only, and its terms assumed that some merchants might refuse to enter this association, although a whole century earlier an emperor had confirmed the "good customs" of Genoa's inhabitants. But during the 12th century the communes were given shape by their external relations. Some received privileges from the emperor, e.g., Pisa and Genoa in 1162, which recognized their right to elect their consuls; others formed the Lombard League (q.v.; 1167) against the same emperor, Frederick I Barbarossa. Long before this the towns had embarked on the conquest of the surrounding countryside in the attempt to secure their food supplies and to extend the area rendering them fiscal and military aid. The ecclesiastical diocese was recognized as the natural boundary to which the city could lay claim, but inevitably there were soon territorial and other disputes (Milan was at war with Pavia and other Lombard towns by the mid-12th century), and neighbours tended to become enemies. This was the great age of the citizen militia, in which nobles fought on horseback and non-nobles on foot, and the ceremonial *carroccio* (q.v.) was drawn into battle as the emblem of municipal patriotism. The main task of the commune was then to secure the submission of neighbouring feudatories and rural communes, and the overlordship thus gained set the town a new task in government.

**The Podestà.**—The last decades of the 12th century saw the breakup of the consulate in many communes. After the commune had asserted its right to exist, temporarily dormant differences of interest within the governing class tended to emerge, and this was a time of bitter disputes. Moreover, there were difficulties about the diplomatic representation of towns by a consulate which was often divided and whose juridical position was not yet fully accepted by the emperor. Already at the peace of Venice between pope and emperor (1177) a number of communes were represented by a single *rector* or *potestas* (*podestà*). The advantages of granting the supreme executive position to a single individual whose position transcended the quarrels of the local consular class were soon recognized, and the institution spread rapidly. It is found at Pisa c. 1169, at Perugia in 1177, at Milan in 1186, at Piacenza in

1188, at Florence in 1193, at Siena in 1199; by the early 13th century it was almost universal. At first it alternated with the consulate, but the consuls are rarely found after c. 1210. Soon it became normal to select the *podestà* from another town (not usually a neighbouring one) to ensure his neutrality in local disputes. He came with his own household, took an oath on arrival to serve the commune loyally and held his position for a fixed period, which was usually six months or a year. The *podestà* was a noble, and he needed a legal training. His office became a recognized profession, in which able men specialized, traveling on from one post to the next.

Naturally the commune did not convey full powers in all matters to this alien "city manager." The councils, though summoned by the *podestà* and presided over by him, retained control of internal and external affairs. The conciliar structure varied greatly from town to town and was the subject of constant experiment (as were methods of election). Most commonly there was a great council (the *de facto* heir of the parliament) and a small, inner "secret" council (*di credenza*). The great council might have as many as 800 members (as at Milan), while the smaller council occasionally numbered 100 (as at Parma) or even more, though its size was frequently limited to 24 or even 16. In addition to the regular council, a large part in communal government was played by *ad hoc* commissions (*balie*), which were often granted special powers in military, financial or constitutional matters.

**The Popolo and the Capitano.**—During the age of the *podestà* (roughly the first half of the 13th century), power normally remained with a governing class roughly similar in composition to that body of minor nobles—and, occasionally, merchants—which had formed the 12th-century commune. It was natural, however, that trade and finance (and, to a lesser extent, the fortunes of agriculture) should bring to the fore some men whose ancestors had not ranked among the *boni homines* and consuls. This was particularly the case in a period in which good luck and skill in overseas trade and in banking might make a man a great deal of money in a short period. Furthermore some noble families tended to recede in financial and social importance. In such a situation there was no possibility that a closed oligarchy could retain power for itself by "freezing" the constitution. New men were always coming to the fore and requiring for reasons of finance and prestige to receive a share in the government of the commune. The governing class was rarely officially sealed against new entrants, but if it failed to absorb newcomers with sufficient rapidity, it found its position threatened. The institution through which the men excluded from power expressed their ambitions was the *popolo*. The *popolo* was a sort of "pressure group" organized as a *societas* and possessing its own military structure. Essentially the organized body of nonnobles, it was frequently closely connected with the guilds (*arti*) and was divided into local regional groups, as well as craft bodies. The earliest popular societies emerged in the Lombard and Piedmontese towns in the late 12th century and early 13th, but they did not commonly capture a considerable share of political power in the commune until around the middle of the 13th century. They then often gained a position whereby, either formally or informally, they took a large part in government: as early as 1229 the general council at Modena had to include representatives of the guilds and popular associations, and four years later half the offices at Piacenza were allotted to the *popolo*. Elsewhere the *popolo*'s institutions often existed side by side with those of the commune and exercised power in rivalry with them.

At the head of the *popolo* a conciliar body, whose members (analogous to the consuls) were usually styled *anziani*, was often superseded by a single official, comparable with the *podestà* (he was normally from another city), namely the *capitano* or captain. The *capitano del popolo* is found at Milan in 1240, at Parma in 1244, at Florence in 1250 and very soon after this in many other towns. Later the *capitano* might in turn lose his predominance to a body of *anziani*: after 1282 the Florentine *capitano* was overshadowed by the six priors representing the seven major craft guilds.

The main *raison-d'être* of the *popolo* was the neutralization of

the social power of the "magnates." This process was pursued largely by legislation denying magnates official position and preventing them from overawing the weaker elements in the population: the declared aim of the Bolognese statutes of 1282 was "that rapacious wolves and meek lambs should be able to walk with equal steps." There was, however, no wholesale dispossession of the original governing class, nor did "popular" gains secure advantage for the workers, the *popolo minuto*. The *popolo* sought to compensate by unity for lack of social prestige and military strength, but it was only one of a number of organized associations struggling to assert themselves within the all-embracing commune. Among these were the family-groups (*consorzio*) of nobles and—linked with them—the Guelph and Ghibelline parties, societies of magnate families whose feuds had become assimilated into a greater system through their polarization by the two magnets of medieval Italy, the empire and the papacy.

**The Rise of the Signori.**—The history of all the Italian communes was turbulent, both internally and externally. Warfare was constant, and mercenary cavalymen, many of them nobles exiled from their home towns by the hostile faction, had superseded the militia. Constitutional arrangements were unstable. Dante likens Florence to a restless man, shifting constantly because he cannot get to sleep. The willingness of the *popolo* to accept a single leader has already been mentioned, and in any crisis, military, financial or political, men were liable to entrust their cause to one able and ambitious individual. Constitutional precautions against prolonging the period of office of a *capitano* or *podestà* could be set aside. Nor were men lacking who sought to subvert republican institutions. Feudal lords and dependents of the Hohenstaufen or Angevin rulers, demagogues, successful mercenary generals, were all prepared to accept office as a town's lord (*signore*) with special powers which were at first temporary but might be prolonged to life tenure and ultimately inherited by a son or other relative. In times of bitter factional dispute republican political processes, slow and lacking both secrecy and continuity, had obvious disadvantages. Hence Guelphs, Ghibellines and popular parties tended to turn to a single saviour. The earliest significant *signorie* appear in Venetia and Lombardy in the middle years of the 13th century: by 1237 Frederick II's ally Ezzelino da Romano was holding both Verona and Padua, and by 1255 Oberto Pelavicino was *signore* of Cremona, Piacenza and Pavia. From 1258 mastery at Milan alternated between two rival families, the Della Torre and the Visconti. The earliest Tuscan *signorie* are those of the *condottieri* Uguccione della Faggiuola at Pisa and Lucca (1313–16) and Castruccio Castracani, also at Lucca (1320–28). By that period the *signorie* had become the rule rather than the exception, and lords were accepting imperial or papal titles or vicariates to legitimize their position. Where republicanism survived it did so through the control of a tightly knit oligarchy. Florence, after a series of oligarchies had dominated the commune, submitted from 1434 to the Medici, though their position as formal *signori* was confirmed only much later. Venice, where membership of the great council was "closed" from 1297, was the only Italian city-state that continued to be a republic into the modern period.

#### SOUTHERN FRANCE

In Provence and Languedoc the Roman towns and the custom of nobles living within them survived, and in consequence communes arose in circumstances in some ways analogous to those prevailing in Italy. The institution of the consulate is found in many of these towns, and some, such as Toulouse, Avignon and Beaucaire, secured the subordination of certain neighbouring feudatories who became their "vassals." In the course of the 13th century, however, the counts of Provence and the French kings reduced these communes to a dependent position: they had never achieved the full political autonomy of their Italian counterparts. The development of the commune of Toulouse illustrates well how the towns depended on the external situation for the acquisition of self-rule. At Toulouse the counts were willing to part with much of their control over justice, economic life and internal policing in return for the commune's alliance, particularly during the period of the count's resistance to the French crown (1226–29). After this

time, and particularly under Alphonse of Poitiers (1249-71), Toulouse lost its former status and liberties.

### FLANDERS

The greatest towns of the Low Countries, Ghent, Bruges, Ypres and Arras, rivaled the biggest north Italian cities in size during the later middle ages. In the same area as these major places were a number of other towns—such as Douai, St. Omer and Brussels—of considerable economic importance. Farther to the southeast lay Liège, Huy, Namur and Dinant. The Flemish towns were situated in a zone specially suited to become a centre of commerce, for they were at the meeting point of four major routes. London and other English ports lay close at hand. To the east there was easy access to the Rhineland and the other German towns and, by sea, to the Baltic. Sea routes to the west connected Flanders with the Atlantic coasts of France and Spain and, in the later medieval period, the Mediterranean. The main connection by land was to the south, with Champagne, Burgundy and eastern France and, by Alpine passes, with Italy. This was the principal link with the Mediterranean until galleys opened up the sea route at the end of the 13th century; in the earlier period Champagne (*q.v.*), with its fairs, was a great centre of exchange. Trade was the first *raison-d'être* of these towns and brought them to life again in the 10th century after a long period during which they had been almost effaced by Viking inroads, but in the 12th-14th centuries most of the towns—Bruges was an exception—owed their greatness less to commerce than to textile manufactures; again the proximity of England was an all-important factor, for English wool was that most used for the looms of Flanders. The population of the industrial towns rose rapidly, and local production became inadequate for their food supply; they were dependent on the grain of eastern Germany and northeastern France. By the middle of the 14th century Ghent probably had more than 50,000 inhabitants, and Bruges was of comparable size. The dominance of a single industry was, however, a danger. At Ypres in 1431 more than half the workers were engaged in cloth manufacture, and already the town had been severely hit by the rise of the English industry.

Their political situation facilitated the acquisition by these towns of semiautonomous institutions. Most of them lay within the zone of the counts of Flanders, who held the territories west of the river Scheldt as fiefs of the French king and those to the east as fiefs of the emperor. The counts, however, lost many of their French-speaking subjects to the French kingdom: Artois as a dowry in the late 12th century; Lille and Douai in 1312. The great advantage of the towns was the comparative weakness of the counts, who were willing to grant privileges in return for financial and military support. This was particularly the case in times of disputed succession or division within the comital family: for example, after the murder of Count Charles the Good in 1127, when the towns helped Thierry (Dietrich) of Alsace to succeed; and again after the cession of Hainaut to John of Avesnes (1256).

Ghent, which grew up at the confluence of the Scheldt and Lys, provides an example of the emergence of a trading community and of the institutions that such a community required and evolved. There had been an abbey and probably a trading settlement at this site in the early Carolingian period. It was raided and occupied by Vikings but revived after Count Baldwin II the Bold built a castle there *c.* 900. A new *portus* of traders grew up around this castle and another round the abbey of St. Bavon, one kilometre away, where an annual fair was held early in the 11th century. By the end of that century the two *portus* were linked; Ghent had four parish churches, and its cloth industry was starting to develop. Such a body of traders and craftsmen could not be content to remain under the normal feudal jurisdiction of the count. They needed exemption from feudal services, the right to mortgage their property and the power to make their own arrangements concerning market regulations and local taxation; above all they had to have jurisdiction in a special court applying a particular type of law to itinerant merchants who needed quick justice. The burghers were organized in a guild merchant and in craft guilds and themselves evolved institutions for mutual assistance; the

man who was untrue to his oath binding him to the other burghers was driven into exile.

**The Échevins.**—The process whereby the counts granted a degree of self-government to these communities was a simple one. The Carolingian institution of a local class of law-worthy men known as *échevins* (*scabini*) acted as the bridge. In the first place a town had its own *échevins* (usually numbering 12 or 13) who judged according to the town's law while remaining magistrates of the count. Insensibly their position altered, and they tended to become the judicial and, ultimately, also the executive representatives of the town itself. An important stage in this development was reached when the commune claimed the right to appoint the *échevins*. Nominally the count continued to appoint, but the burghers themselves made the choice *de facto* in many towns. The institution of the *échevinage* was transformed in another way by the towns: beginning as a status conferred for life, it became an annual office when it fell to the control of the burghers. The date of this change, which approximately marks that of the commune's ascendancy, is 1194 at Arras, 1209 at Ypres, 1212 at Ghent, 1228 at Douai, 1235 at Lille and 1241 at Bruges.

The *échevinage* could become the council of the commune only when the count permitted it to usurp what had been the authority of his castellan or bailiff. Where the lord resisted communal claims—as the bishop of Liège did in his own city and at Huy, Dinant and Maastricht—the burghers instituted a rival office to the *échevins*, namely the *jurés* (*jurati*). In such circumstances the *échevins* maintained control over justice, though the bishop's authority might be checked by the competence of the *jurés* in some municipal matters. This was the situation also at Cambrai, where a 50-year struggle ended in favour of the bishop after 1227.

The Flemish towns did not win great territorial "counties" like the Italian republics, but they did assert their authority in the immediately neighbouring "flat land." In 1314 Ghent forbade the production of cloth within five leagues of the town, and similar regulations were enforced elsewhere. Bruges would not permit money-changers to do business at Sluis, its own seaport. The policy of the communes, as in Italy, was normally dictated by the class of prominent citizens known to contemporary writers as *majores*, *ditores* (the wealthier), *boni homines* and so on. In many places craftsmen were formally debarred from the *échevinage*, and normally a system was evolved combining the rotation of offices with a patrician monopoly. Even this was vulnerable and might be the victim of a clique within the patriciate itself: at Ghent, from 1228, 39 *échevins* were installed in power for life, the 13 *échevins* of each year being accompanied in office by those of the two preceding years.

In the period of Flemish decline the patricians were seriously challenged by the craft guilds, till both parties had to yield before the Burgundian dukes and their successors. Even in the 13th century there were occasional strikes and (in 1274) an attempted rising against the *échevins* of Ghent by the weavers and fullers. At the beginning of the 14th century the artisans found the count an ally against the coalition of Philip IV of France, and the Flemish patricians. The battle of Courtrai (1302) saved the former party, and throughout the 14th century the crafts held on to their tenuous advantage. The constitutions of most towns were now altered in such a way as to give representation to the craft guilds, the minor trades combining in "members." After 1368 Ghent had a fixed organization of three "members," of which one consisted of *poorters* (merchants, etc.), one of weavers and fullers, and one of the small craftsmen; the *poorters* chose three *échevins*, the other two members, five each. Flanders' relative economic decline in this period played its part in this weakening of the oligarchy. Under Jacob van Artevelde the weavers of Ghent for a time (1338-45) used the economic and diplomatic link with England to dominate all Flanders. These courageous men suffered defeat after defeat, but by the 15th century the towns themselves never skilful at looking beyond their own immediate interests, began to yield before the encroachments of the centralizing state. Other areas were now coming to the fore economically, in particular Holland and northern Germany, but the towns could still furnish much wealth to the Burgundian dukes. Bruges fought about

against Philip the Good in 1436-37, and Ghent did so in 1452-53. The last flicker of the old municipal spirit in Flanders was the unsuccessful revolt of Ghent against Charles V in 1539-40.

### NORTHERN FRANCE

In the French kingdom, excluding the areas of Flanders, Provence and Languedoc (mentioned above), characteristic communal institutions developed, although the towns achieved only a limited degree of self-government. A commune or *conjuratio* was formed in many French towns in the 12th century and in some as early as the 11th. The circumstances leading to this development were often, but certainly not always, revolutionary. The revolt was often against an episcopal lord (as at Laon in 1112), though in some cases a lay lord was involved: in 1070 the men of Le Mans rose against the duke of Normandy, taking advantage of his absence in England, "and they made a conspiracy which they called a *communio*" (says the chronicler) "binding themselves to each other by oath." This sworn association, which was the essence of the commune, did not necessarily arise in a time of violence or crisis. Its purpose was to ensure internal security, justice and order, to bring about conditions under which the markets and crafts could develop and flourish. Thus the inhabitants of the town swore to give each other aid at times of need and threatened the destruction of their home, or even expulsion, to those who were false to the oath. The oath was compulsory for all members of the commune. Those who had taken it, the burgesses, were the *jurés*, like the men of Beauvais "dwelling within the wall of the city and in the suburbs" who, as their charter says, "had sworn a commune." These communities were often small and their members primarily agriculturalists and craftsmen.

With the grant of royal charters and privileges the French communes emerged from obscurity, but the association was already formed (except in the case of new foundations) and might already possess its own "good customs" (those of Tournai were confirmed by Philip II Augustus' charter of 1188). From the point of view of the recipient, these charters were mainly promises of protection against unjust treatment by royal officials and in particular of alleviation of arbitrary demands for services and money. If the grantor was a lay feudatory or prelate, the charter might represent a compromise with the commune concerning jurisdictional powers to be exercised by the two parties. But the lord was often the king himself, and to an increasing extent it was the crown that shaped the development and limitations of communal institutions in France. To the king the commune was a promising source of military and financial strength and a potential ally whose anti-baronial interests overlapped with his own so long as it received privileges which made of it a satisfied but not overmighty subject. From the king's point of view the commune was "a collective feudatory," whose representatives took an oath to him, the terms of which resembled closely feudal oaths of homage. By the reign of Philip Augustus (1180-1223) at least 39 towns owed military service to the French crown, most of them providing some mounted troops or money in lieu. Poitiers owed the king service "beyond the Loire in the same places as the royal feudatories of Poitou." At the fateful battle of Bouvines (1214) Philip had the assistance of the militia of Beauvais, Corbie, Amiens, Compiègne and Arras. Many towns also rendered feudal "aids"; Abbeville, for example, had the obligation of paying 100 *livres* when the king required to be ransomed and when his son was knighted or his daughter married. The strategic use of the towns was a fundamental aspect of the policy of the counts of Anjou, and in this, as in other ways, the French were willing to learn from the Angevins. Philip's charters went mainly to towns situated near the frontiers of his domain. The communes could aid him against hostile feudatories, as did Dijon against the duke of Burgundy. The towns whose functions were most specifically military were the *bastides* (*q.v.*) created by the king and other lords. Where the purpose of the foundation was mainly economic it was more often known as a *ville-neuve*.

The officers of the French communes were known as *jurés pairs* or *échevins*, and the towns normally had one or more councils. They differed from their Flemish counterparts in that they had a

single leading official, usually known as the mayor (*maire*). The mayor, however, was not always chosen by the commune. At Rouen he was selected by the duke of Normandy from a list of three drawn up by the council of 100, and similar methods prevailed in many other towns. As elsewhere the positions of importance were inevitably monopolized at first by a patriciate. "The rich men possess rule in the towns," says the sire de Beaumanoir, the 13th-century legal writer, but he goes on to describe "many disputes. . . the poor against the rich and the rich against each other." As in Flanders, the craft guilds usually succeeded by the later medieval period in breaking into the merchants' monopoly and in securing representation in the commune's offices. The role of the monarchy in recognizing and fostering the communes also gave it the opportunity of intervening in the towns and ultimately of depriving them of most of their independence. In the second half of the 15th century, after the end of the Hundred Years' War, the French kings, by favouring compliant oligarchies, achieved the same centralization at the expense of the communes that their Burgundian neighbours had carried out a little earlier in Flanders. After Louis XI's reign (1461-83) the very concept of a "commune" withered away, though the *villes à échevinage* lingered on.

### GERMANY

In certain features the development of urban institutions in Germany resembles closely that of Flanders and northern France. The most distinctive aspects of the medieval German commune are the important role of royal and princely founders and the consequences, in the later period, of the weakness of the monarchy, the towns then joining in leagues that sought to enforce law and order and to weaken the competing power, the territorial princes.

In many western German towns near the Rhine, such as Cologne, Mainz and Worms, occupation was continuous from the Roman period, though there was a break in local institutions. The nucleus of the later commune was normally the settlement of traders (*Wiek*), growing in size and importance during the Ottonian and Salian periods (936-1125) as commercial contacts with the Baltic and Slav areas increased, as German settlement in the east extended and as the merchant's way of life became less peripatetic. These trading communities, in which some quasi-political functions were normally exercised by the guild merchant, fostered their internal peace by an oath binding the burghers to mutual protection and brotherhood, forbidding private vengeance and threatening exclusion for those breaking the oath. Sometimes the earliest reference to a *conjuratio* suggests an association formed for specific action, particularly against an episcopal lord (as at Worms in 1073, at Mainz in 1077, at Speyer in 1101-11 and at Cologne in 1106 and 1112). Even when there was no such purpose the commune inevitably tended to accrete powers extending to economic regulations, taxation for the upkeep of defenses and the right to demand military service from the burghers. The merchants also required their own law giving their market special protection and granting them freedom to alienate land, etc. Through their possession of a separate law and their police powers the towns acquired much jurisdiction and often put forth a formidable mass of legislation.

The great expansion to the east was accompanied by the foundation of communes, though this movement was by no means confined to newly settled territories. About 50 communes are known to have achieved recognition before the end of the 12th century, and the number had increased by about 500 by the end of the 13th. The greatest founders were the higher nobles. Typical foundations were that of Freiburg im Breisgau by Duke Berthold III of Zähringen (1120) and of Lübeck by Duke Henry the Lion of Saxony (*c.* 1158). In each case the site was already settled, and the founder chose to grant privileges to an existing community in return for financial and military advantages. Freiburg, intended to act as a market centre for the trading routes passing through the Black forest, recruited merchants from all southwestern Germany; the duke accepted, or may actually have organized, its *conjuratio*. Lübeck, destined to an even greater future, was already a Baltic trading station before Henry the Lion privileged it, setting up its merchants with burgage building plots. Most of the "new" towns were intended as markets for local crafts rather than as

centres on main trading routes, and landowners and *ministeriales* often remained an important element in the population.

In the *Rat* (council) the commune's officials bore the titles—which seem virtually synonymous—of *échevins*, *jurés* or consuls. The last of these, an importation from Italy, is found at Lübeck in 1201, Erfurt in 1212 and Freiburg in 1218; soon after this it had become general in the Rhineland, Saxony and Swabia. These officers were normally appointed for a year and frequently numbered 12 (occasionally 24). There was also commonly one head official, the *Bürgermeister*. Town charters normally confirmed the constitutional status of the *Rat* and sanctioned the principle (which defended the town's population against erstwhile lords) that residence in the town for a year and a day conferred freedom. In Germany, as elsewhere, a patriciate tended to gain control of the towns in the earlier period, but during the 14th century this monopoly was diluted, the crafts normally securing representation in the *Rat*; e.g., there was an equal share between patrician and guild representatives at Freiburg, Strasbourg, Zürich, Vienna and Mainz.

Royal policy in Germany missed an opportunity in failing to foster the communes. Frederick II went so far as to legislate (ineffectively) in 1232 against all urban (and interurban) "leagues and communities." With the breakdown of central power after Frederick's death (1250), the towns attempted to supply the need for an institution that would preserve the peace and protect their interests against the nobles. The Rhenish confederation of 1254–57 finally numbered more than 100 members. The Hanse towns, the cities trading in the Baltic under the leadership of Lübeck, were co-operating long before the official formation of their political league in the 1350s (see HANSEATIC LEAGUE). A league of Swabian towns formed in 1376 united with a new Rhenish league in 1381, but despite the rise to commercial and industrial greatness of some south German towns, such as Augsburg and Nürnberg, the princes were generally successful (save in the Swiss confederation) against the towns, which were divided and gained no imperial assistance.

### ARAGON AND CASTILE

During the reconquest many Spanish towns were founded by the Castilian and Aragonese kings and by lay and ecclesiastical lords in territory previously under Muslim rule. The purpose of this movement, which was at its height in the 12th century, was to provide military, administrative and economic centres for newly colonized areas. The privileges (*fueros*) granted to these towns made of them "judicial islands" with their own law and market regulations. The status of these communes favourably affected that of the older Christian towns, but most of the Iberian towns gained no great degree of independence; there, as elsewhere, the organization of the town as a community in some ways made it easier for the lord to enforce his will. Altogether exceptional was the position of the great port of Barcelona within the countship of Barcelona under the Aragonese kingdom. The formation of *hermandades* (fraternities) between towns is a phenomenon closely comparable to the leagues of German towns. The major Castilian *hermandades* appeared at times of royal weakness: for example, in 1282 (first *hermandad general*); in 1295 (many *hermandades* formed, that of León and Galicia having 33 members); in 1296 (the "sea-alliance" of Cantabrian coastal towns); in 1313; and in 1315. The normally close link of the towns with the monarchy in Spain is illustrated by their role in the parliaments of Aragon and Castile. Town representatives were summoned to the *Cortes* of León in 1188 and to that of Catalonia in 1214. They were called at least ten times to the Castilian assembly during the reign of Alfonso X (1252–84) and often by his successors. As early as 1283 the towns of Catalonia secured a promise from their ruler that they would be consulted annually.

**COMMUNE (OF PARIS, 1871)**, the name given to the insurrection in Paris which lasted from March 18 to May 28, 1871. It is difficult to determine the relative importance of the various causes of the Commune. The revolutionary tradition of a section of the Parisian population, which had been revived toward the end of the second empire by the struggle of the republicans against the government of Napoleon III, was exacerbated by an exceptional concurrence of circumstances. In Feb. 1871 the people of Paris were exhausted and enervated by the physical and mental suffering of a long siege (see FRANCO-GERMAN WAR). Cut off from contact with the provinces for four months, they did not react to events in the same way. The election of a national assembly with royalist tendencies, composed of deputies from the rural areas, aroused their fears that the monarchy might be restored. The occupation by the Germans of a part of Paris inflamed their patriotic sentiment. Moreover, the assembly committed the error of canceling the moratorium on rents and bills and terminating the payment of national guardsmen. The feelings of Parisians were further wounded by the assembly's decision to sit at Versailles.

In order to maintain order Adolphe Thiers, who was head of the executive of the republic, decided to disarm the national guard which had constituted itself into a "republican federation" with its own central committee; hence the name *fédérés* given to the soldiers of the Commune. On March 18 Gen. Joseph Vinoy attempted unsuccessfully to remove the cannons of the national guard parked at Montmartre and at Belleville. Some of Vinoy's troops went over to the insurgents, who shot two generals (Claude Martin Lecomte and Clément Thomas) who fell into their hands.

At the insistence of Thiers the government withdrew to Versailles. Confused negotiations then took place between the central committee and the *maires* of Paris on the one hand, and the *maires* of Paris and the government on the other. However, the heated atmosphere in which they were held rendered the negotiations abortive. Municipal elections arranged by the central committee took place on March 26. Those elected, dominated by extremists, formed themselves into a "Commune of Paris" from which the moderate elements withdrew. When the news of the insurrection became known "communist" movements on a minor scale broke out at Lyons, St. Étienne, Toulouse, Narbonne, Marseilles, Limoges and Le Creusot, but were immediately suppressed.

After the withdrawal of the moderates the Commune comprised 17 members of the international (notably Gustave Lefrançois, Eugène Varlin and Léo Francel), mainly men of the artisan class who wanted social reform by legal means; 8 supporters of Auguste Blanqui (q.v.), who favoured a social revolution through insurrection and dictatorship; 8 members of the central committee (including Varlin and two Blanquists), chiefly concerned with military action against the government at Versailles; and about 30 men belonging on the whole to the revolutionary tradition of 1793 (such as Louis Charles Delescluze, Félix Pyat [qq.v.], Jules Miot and Charles Ferdinand Gambon), who were for the most part men of the middle class—journalists, students or clerks. Apart from half-a-dozen *déclassés* (such as Jules Vallès, Raoul Rigault and Charles Théophile Ferré [q.v.]) and two who were mentally unbalanced, they were honest men, fanatical, full of illusions and without experience.

Within the Commune, in which men of middle-class origin were more numerous than those from the working classes, there were two distinct trends. The larger group, chiefly middle class, was centralist in outlook and favoured a Parisian dictatorship which would impose its rule on the whole of France. The other, predominantly working class and inspired by the international, wanted to set up a federation of equal communes throughout the country. At no time did the Commune succeed in forming a coherent leadership (Blanqui, who might have headed the movement, was in prison in the south). It was divided into commissions (executive, military, general security, finances, justice, labour, industry and trade, public services, education and external relations), the chief of these being the executive, which was dominated by Blanquists. The Commune did not find the time to deal with social reforms. The central committee of the federation of the national guard wanted to keep control of military matters in its own hands, and this involved it in a dispute with the leaders appointed by the Commune. There were in all 30,000 effective combatants, but they were never properly organized.

Thiers raised an army of 130,000 under the command of the marshal de MacMahon. The latter moved slowly and his troops took the offensive on April 2. On the following day at Rueil, Bellevue and Villacoublay the *fédérés* attempted a sortie, but this showed that they were incapable of mounting an offensive. MacMahon's troops captured the fort of Issy on April 30, the fort of Vanves on May 14 and entered Paris through an undefended section of the town on May 21. It took the army seven days—"la semaine sanglante"—to reconquer Paris. The *fédérés* put up a courageous defense, establishing barricades and setting fire to public buildings before withdrawing. The last battles took place on May 28 in the Père Lachaise cemetery (where an annual ceremony of remembrance is still held).

During the final week's fighting the Communards executed about 60 hostages, including the archbishop of Paris, Georges Darboy. The regular troops shot a large number of insurgents captured in arms. The total number of deaths caused by the insurrection is unknown. Estimates vary from 17,000 to 36,000 but 20,000 seems a likely figure. After the suppression of the Commune there were 38,000 arrests. The courts-martial which were set up sentenced 270 people to death (there were, however, only 26 executions), 410 to forced labour, 3,989 to transportation to a restricted area, 3,507 to simple transportation, 1,259 to special detention, 3,398 to terms of imprisonment, 322 to banishment, 117 to surveillance by the police and 9 to fines; 56 children were sent to reformatory institutions. Those sentenced to be transported were sent to New Caledonia. The repression affected the *faubourgs* or outlying quarters of Paris in particular, that is to say the districts inhabited by petty craftsmen; more than 50% of the painters, tilers, lead-workers, zincworkers and shoemakers, and 30% of the cabinet-makers disappeared. Karl Marx, however, saw the Commune as an episode in the struggle of the organized proletariat.

There were two amnesties, the first on Jan. 17, 1879, and the second on July 19, 1880.

**COMMUNICATION** has several different and equally acceptable meanings, but no better English word has been found to denote a process both interactive and purposeful. "Communication" derives from the Latin *communicare*, "to make common, to share, to impart, to transmit." In this article the interpretation of making common or sharing of something between two or among several persons or groups of people is preferred. This definition stresses the interaction that distinguishes communications from other messages, and stresses the effects of a message. Only by the appreciable effects of, or reactions to, a message can a communication be distinguished from a message that is both understood and rejected.

The relations between the purposive and interactive functions of communications have been clarified by analogies with automata, such as servomechanisms. (See **INSTRUMENTS, ELECTRICAL**

**MEASURING: Recording Instruments; INFORMATION THEORY.**) The purpose of the thermostat, for example, is to keep a room at some wanted temperature, a function it performs by reacting to lower temperatures so as to trigger the heating system, and to higher ones by closing the heating and starting the cooling system. This process also appears in the instinctive adaptations to environmental changes as made by such biological organisms as the termites, and in the international relations of a democratic state whose government receives wide popular support and is served by an efficient intelligence organization.

Communication applies to each of these examples, from the thermostat to the national government, insofar as the reactions to its messages or questions enable the system or organization to maintain the direction of its efforts toward the efficient accomplishment of its purposes.

**Sources of Evidence.**—As a life process, communication extends beyond the frontiers of present knowledge and so beyond the range of present social controls. Hence this article attempts merely to outline the process with reference to the frontiers and to suggest some effects of public communication upon contemporary institutions and affairs. The communication process has been most profitably studied in such particular biological organisms as bees and termites (see **SOCIAL INSECTS**). The processes of public communication, as affected by developments of the mass media within the 20th century, have been more clearly explained in such particular situations as a general election than they have been explained by reliable theoretical principles.

A theory of public communication sufficiently valid to support reliable predictions concerning even the short-run effects of public communications on public issues, e.g., information campaigns, is still far to seek.

Evidence contributing to a general theory has been supplied by a wide range of arts and sciences, ranging from the arts of rhetoric and literary criticism through the biological and social sciences to mathematics. The need to synthesize and integrate the evidence supplied by each of the many contributing sources is stressed by most workers in the field. One of the more successful attempts to meet this need was made by Kenneth P. Adler in *The Communication Process* (1959), the bibliography of which includes works in philosophy; the rhetorical, dramatic and literary arts, in part applied by linguistics and semantics; learning theory; Gestalt psychology; psychoanalytic psychology; sociology; political science; psychophysics and mathematics; theoretical models; and communication effects.

**The Public-Communication Process.**—A bird's-eye conspectus of the process emerging from this wide range of evidence is afforded by Wilbur Schramm's chapter: "How Communication Works" in *The Process and Effects of Mass Communication* (1954). The substance may be partially represented by the diagram.

The initial component of the process is an idea or impulse in the mind of the sender; the idea may or may not be sufficiently clear to be communicable to the receiver. The second component is the formal expression (encoding) of the idea, which constitutes the message, or signal. The third component is the receiver's interpretation (decoding) of the message as received from the sender directly, and also as received indirectly via the various publics concerned with the issue; for example, in a national steel strike, messages between the union and management have such publics as congress, chambers of commerce, manufacturers needing

SCHEMATIC DIAGRAM OF COMMUNICATION PROCESS. (\*PUBLICS ARE GROUPS ASIDE FROM THE SENDER AND THE RECEIVER WHO RECEIVE MESSAGES INDIRECTLY. See TEXT)

steel, other unions, and, of course, the public at large. The fourth component consists of the receiver's response to the message, reactions which may or may not come to the attention of the sender of the original message. If they do, they constitute a fifth component, the "feedback"; and the sender's interpretation or decoding of this response to his message would complete one round of the communication cycle. This one round is sometimes decisive, as when one world power states an issue of global importance and receives a clear answer from another world power. Normally this first round is merely preliminary to many other rounds, each adding something to what both the sender and the receiver previously knew about the other's position and hence about the possibilities of some mutually satisfactory compromise. Such interactions may, of course, serve both to sharpen hostilities and to compromise them.

Evidence supplied by the various branches of knowledge mentioned above concerns each component of the process as oversimplified by Schramm's conspectus. For example, the second component—expressing an idea persuasively to a given audience—has occupied many of the best minds of all ages and all cultures. The bare bones of the evidence include: (1) how to compel attention to the message, involving many of the forensic, histrionic and literary arts as developed and variously applied by different civilizations and cultures; and (2) how to carry the message to the given audience. The latter involves the techniques of adapting the message so closely to the dominating values, motives and aspirations of the audience that the audience is inspired and eagerly welcomes the message. Implications of similar depth and scope could be stated with reference to other components of the communication cycle, and particularly with reference to the role of the audience. The influence of audiences upon the public communications they receive is apparently greater than the influence of the communications on the audiences.

**The Communication Revolution.**—Fairly comparable with the Industrial Revolution (1750–1850) in its effects upon socioeconomic and political institutions is the world-wide impact of mass media, such as wireless transmissions of spoken words and photography in natural colours. The technologies developed at the outset of the 20th century enabled millions to hear, see and read the same messages at about the same time, whereas only hundreds could do so before; and the communication revolution is, in the second half of the 20th century, far from completed. The high costs of installing and operating the mass media could be offset only by obtaining a favourable mass response; e.g., television in the U.S. To obtain this response, great efforts were made to discover what the masses most wanted to be told or shown and then to tell or show them just that. The new mass media were indeed revolutionary to the degree that they shifted the origin of mass messages from prominent individuals—statesmen, scholars, popular authors and others—to the masses themselves.

**Effects of Public Communication.**—The effects of messages via the mass media are naturally more interesting to more people than any other aspect of the communication process: they have accordingly been most diligently investigated. Franklin Fearing, "Social Impact of the Mass Media of Communication," chapter VIII of *Mass Media and Education* (1954), the 53rd Yearbook, Part II, of the National Society for the Study of Education, makes the following appraisal of the evidence to date:

(a) The responses to content of the mass media of communication are determined by a large number of factors, only one of which is the content itself.

(b) More specifically, the relationship of the interpreter to content has the characteristics of perception, the course of which is determined by his need-value-motivational system, the total situation in which the process occurs, and the content. [Fearing uses "interpreter" to mean what has been here called "the receiver of the message" or "the audience."]

(c) The outcomes ("effects") of exposure to particular content are extremely diverse and cannot be predicted in any particular case except on the basis of comprehensive knowledge of the content itself, the need-value system of the interpreter, and the characteristics of the total situation as perceived by the interpreter.

(d) The outcomes or impact of exposure to content may or may not take the form of overt behaviour.

(e) Whatever form the response to content may take, covert or

overt, it is always dynamic in the sense that it serves the social-psychological needs of the interpreter.

(f) In general, the content of the mass media reflects existing value systems of the society in which they occur.

Among the plausible effects of public communications the following are generally assumed: (1) integrating the society by promoting consensus on basic policies; (2) stabilizing the society by supporting majorities against dissident minorities; (3) facilitating public administration by advising officials of community problems and advising citizens of official policies and actions; (4) strengthening national defenses by reporting both external and internal threats to national security; (5) extending the range of discourse by popularizing new terms, technical and cultural; (6) reinforcing social customs, such as etiquette or personal health practices; (7) stimulating fads and fashions.

One of several probable consequences of the communication revolution is that public opinions are rather reinforced than changed by mass communications. The changes were and are made largely by interpersonal communications. The conditions that help mass communications change public opinions include the following: (1) when the audience addressed is directly reached by the given medium and is open-minded on the issue; (2) when the content and style of the communication stress events more than opinions, appeal more to emotions than to reason, talk the language (exploit familiar concepts) of the audience, are not blocked by competing communications and attack opposing opinions indirectly; (3) when the media or channels used are personal, are directed at opinion leaders and are specialized; i.e., focused on appropriate interest groups; and (4) when the subject or problem discussed is new, is far away in time and space, is of relatively minor importance to the people addressed and emphasizes the personalities involved. (This outline is based on Bernard Berelson's "Communications and Public Opinion" in *Communications in Modern Society*, ed. by Wilbur Schramm [1948]).

**Institutions Involved.**—All institutions of national scope and many smaller ones, in western cultures at least, were affected by social forces stimulated by the new mass media. Some institutions were largely restructured, or reconstituted, including the basic institutions of government, justice, church, press, schools, commerce and industry. The degree of change in the structure, if not the goals, of each institution was largely proportional to two factors in combination: (1) the extent of arbitrary authority the institution had previously exercised; and (2) the size of the populations directly affected by the institutions. The more authoritarian and widely influential institutions were the more obliged to heed the popular criticism of their operations as the mass media steadily and geometrically increased the number of articulate critics by broadcasting the information needed to make their protests effective. Such institutions as the foreign ministries of major world powers were forced to change their procedures when both the problems and the approaches of "secret diplomacy" were broadcast by the mass media. Mass communication thus tended to move international negotiations from the smoke-filled room to the global expanse of broadcast nationalist propagandas.

Bernard Berelson's over-all generalization of the available evidence on the effects of mass communication is as follows: "The nature of the audience—its social position, attitudes, interests, intelligence, level of information, educational status, personality traits, etc.—has a determining influence on what communications will be given attention; how they will be perceived and interpreted; and what effects they will have." (Letter of Bernard Berelson to Douglas Waples.) This goes far to explain why and how the mass media, during the first half of the 20th century, managed to equalize, occasionally to reverse, the previously top-heavy ratio between the authority of the officers and policy makers of an institution and the proposals supported by the publics affected. Examples may be cited from a few key institutions.

**Commerce and Industry.**—The mass media were naturally first exploited in the western industrialized nations by the advertising agencies, in the other less industrialized nations by the politicians. In between was the British Broadcasting corporation (and its imitators in Australia, Canada and other members of the Commonwealth of Nations), which undertook to protect radio and tele-

vision from control by either commercial or political interests. Because the underdeveloped countries were less able to operate technically efficient services, the effects of the new media upon their institutions were less revolutionary but still apparent. In the industrially developed countries the mass media made the advertising industry so rich that it could spend much more money on communication research than any other institution could afford. Such research enabled the advertising agencies to sell more advertising, and the high-pressure mass advertising doubtless sold more goods and services, with inevitable inflationary effects on the national economies. Market analysis followed by mass advertising proved so efficient in selling commodities at home that the United States government was persuaded to employ similar methods in selling its policies abroad. The evidence so far, as suggested above, shows the effects of mass appeals to be inversely proportional to the seriousness of the issue: the masses are much more easily moved from one toothpaste or cigarette to another of similar quality and price than they are moved by the mass media to change their views on economic, political or other social issues.

The mass markets developed by mass communication had an appreciable effect, in the more highly industrialized nations, upon the relations between management and labour in industries of national scope. Management discovered that wages high enough to enable employees to become consumers of the industry's products paid double dividends. Hence, capitalism, for reasons of self-interest, was inclined, by the leveling effects of the mass media, toward labour policies progressively socialistic.

**Political Institutions.**—The social psychologists explaining the effects of the mass media on commerce and industry also explain their effects on political and other institutions. Mass communication stimulated urbanization; increased both social and geographical mobility; increased impersonality by enabling people to live in a city without any close friends; accelerated social changes. These and other effects of the communication revolution tended to substitute the shotgun for the rifle in presenting public issues to the voters in democratic states. The issues had to be stated broadly in order to elicit a mass response; hence, the more closely analytic (rifle) presentation was discouraged.

The most obvious effect of the mass media on political decisions was thus to substitute centralized propaganda for small group consensus. The mass media substituted stereotypes for statements of opinions based on personal experience, and the substitution had not yet proved advantageous in the second half of the 20th century. Arthur Schlesinger, Jr., asked "... why do we insist on propagating abroad stereotypes which impress few foreigners and have long ceased to represent the American reality." (*The New York Times Book Review*, December 20, 1959, Arthur M. Schlesinger's review of *As Others See Us: The United States Through Foreign Eyes*.)

**The Schools.**—The educational curricula of most modern states normally lag five or more years behind the realities of the technical and social problems that the schools teach the oncoming generations to meet. Historically, the development of educational theory has been guided by successive popular philosophies and social values as interpreted by scholars authorized to prescribe the curricula. The mass media have tended to democratize the authority of scholarship by slanting the curricula of the schools and universities toward what the students want to learn.

**The Press.**—Newspapers, magazines and books have been called slow media. Their mass influence is delayed by the time required to read and react to the reported details of a significant event or to an editorial analysis of it. As an advertising medium the press had certain advantages which it fully exploited. The result was an effort by publications addressed to the general public to write what their readers wanted to be told. In short, the influence of the readers on the press became greater than the influence of the editors on their readerships.

**Conclusion.**—The mass communication media had already by the second half of the 20th century produced important changes in the policies and organizations of many basic social institutions. Further changes may be expected until the effects of public communication on public issues are sufficiently explained to permit

a society to control the effects. Such explanation requires an integration of the evidence supplied by the several fields of knowledge mentioned earlier, the integration required to produce a reliable theory of public communication in the modern world.

**COMMUNION, HOLY**, one of the commonest terms in English for the Christian Eucharist. The Authorized Version translated I Cor. x, 16: "The cup of blessing which we bless, is it not the communion of the blood of Christ? The bread which we break, is it not the communion of the body of Christ?" In strict usage, the term refers to participation in the sacrament and to reception of the elements, but from this meaning it has been applied to the entire sacramental action, especially in those denominations where such practices as the adoration of the Host do not obtain and where, consequently, the sacramental action consists almost completely of eating and drinking in common. See also EUCHARIST. (J. J. PN.)

**COMMUNISM**, a term used to denote systems of social organization based upon common property, or an equal distribution of income and wealth. In the past there were many small communist communities, most of them on a religious basis, generally under the inspiration of a literal interpretation of Scripture (see UTOPIA). Some early or "Utopian" socialists of the 19th century followed a similar course, though they replaced the religious emphasis by a rational and philanthropic motivation. Best known among them were Robert Owen (1771-1858), who founded New Harmony in Indiana (1825), and Charles (François) Fourier (1772-1837), whose disciples organized settlements in the United States after the model of his original "phalanx," the most famous of which was Brook Farm in West Roxbury, Mass. (1841-47). In 1848 the word communism acquired a new meaning when it was used as identical with socialism by Karl Marx and Friedrich Engels (qq.v.) in their famous *Communist Manifesto*. (See also MARXISM.) Communist writers have continued to use the word socialism to denote the type of social order known as communism in English-speaking countries.

Marx did not find the basis for the communist movement in religious or ethical assumptions but in the new social sciences. Living in the century of confident faith in science and of a rapid industrial revolution, he claimed as a disciple of Georg Hegel an infallible certainty for his analysis of the historical forces at work in society. He regarded the changing economic structure as the foundation of social life. He looked upon the industrial working class as the bearer of a new order which would emerge on a world-wide scale as the result of an immanent historical process using the class war as its vehicle.

Because Marx's doctrine was ambiguous on many points, especially regarding its application and the future course of its realization, it gave rise to various interpretations, the most noted being those developed by Russian revolutionaries. Because of the success of the Russian Revolution the term communism became associated in the 20th century with ideas and practices of the Russian Marxists, and particularly of those who became the developers of the soviet system of government.

**The Origins of Communism.**—Communism as developed in

Russia may be traced back to the foundation in 1883 of the Group for the Emancipation of Labour by G. V. Plekhanov and P. B. Axelrod. The latter, deeply influenced by the doctrines of Karl Marx, which were just beginning to exercise a wide influence on Russian socialism, broke with the older Populists, who had counted upon a peasant revolution as the source of Russian emancipation. The Group for the Emancipation of Labour preached the doctrine that the main pivot of revolutionary success must be the organized working class. Because of its consequent emphasis upon the class structure of society the Group may be regarded as the first Marxian organization in Russia.

But it was not until the founding in Russia of a Social Democratic party, later to be called Communist party (see COMMUNIST PARTIES), that the special characteristics of communism as a doctrine matured. Intraparty debate clarified these characteristics. Some members of the party believed that the first essential work was to win working-class adherents by pushing their economic claims to better industrial conditions; the vaster task of capturing the state was, in their judgment, not yet ripe. Others, of whom Vladimir Ilyich Ulyanov, known as Lenin (*q.v.*), was the most outstanding, insisted that economic discontent must be from the outset merely the base from which the capture of the bourgeois state by the working class is organized. The first group (P. B. Struve, S. N. Prokopovich, E. D. Kuskova) insisted that the overthrow of tsarism was not a duty of the working class; the latter should occupy itself with matters like hours of labour and rates of wages. Proponents of this policy were called Economists. Their opponents (Lenin, L. Martov, Plekhanov) were known later as Iskrists from the title of their journal *Iskra* (founded in 1900).

The period from 1898 until 1903 was the most critical in the development of the doctrine of communism, for ideas were in flux. The number of adherents of the new revolutionary school grew as students poured into it from universities and technical schools, founding groups of every shade of socialist opinion. The development, moreover, of liberal bodies like the Union for Liberation, of which Pavel Milyukov was leader, raised in acute form the question of the relationship of the Social Democrats to the radical bourgeoisie. There were problems, further, as to how far it was desirable to encourage those isolated acts of terrorism of which Russian history at this period was so full. The nascent Social Democratic party was then only a loosely confederated system of semiautonomous groups, doctrinally united upon the ultimate goal of creating a communist society as preached by Marx, but with no clear view either of method or of order of priority in objectives.

Debate in the years between 1903 and 1917 clarified the aims and the character of the instrument of revolution, namely the Communist party, whose opportunity to develop communism in practice came in 1917. As to the aims, some party members indicated reverence for universal suffrage and popular determination of the future government of Russia through a constitutional convention. Others, including Lenin, thought such aims secondary and subordinate to the fomenting of revolution; the hegemony of the proletariat seemed to them fundamental. They thought that revolutionary success required dictatorship of the working class over all other elements in society and also sacrifice of the freedoms formulated by the French and American Revolutions as well as of a democratically elected assembly.

**The Consolidation of Doctrine.**—From debates prior to 1917 communism matured as a political doctrine resting upon Marx's assumptions which communist leaders had inherited from the pioneers of 1883. To this Marxian base was added doctrine distilled from experience of the revolutionaries, especially that derived from the abortive attempt in 1905 to seize power from a tsarist government weakened by defeats in the Russo-Japanese War. Fundamental to all communist thinking was the unshakable belief in the inevitable triumph of the working class in revolution and the equally unshakable conviction that to achieve victory the working class must separate itself from bourgeois elements in society and fight them to destruction. Emphasis was upon violence in seizing power and complete denial of the possibility of utilizing parliamentary institutions to achieve working-class aims.

Communism was to be distinguished from Blanquism (see BLANQUI, [LOUIS] AUGUSTE) and terrorism (see ANARCHISM). The former pinned its faith to sudden mass action without regard to time and place; the latter had confidence in the exemplary value of isolated acts such as assassination. The communist was more realistic. A successful revolution, in his view, was the outcome of careful preparation applied to a suitable conjuncture of circumstances. Insurrection, as Marx said, is an art; and Lenin laid down five rules as its guiding principles. Insurrection, first, must never be played with; once it has begun, it must be carried on to the bitter end. When, secondly, the time has been chosen the revolutionists must mass at the proper place forces superior to those of the enemy; otherwise they will be overwhelmed. Once begun, thirdly, the offensive is fundamental, because, as Marx pointed out, "the defensive is death to the insurrection." Surprise, fourthly, is fundamental; and the moment to choose is when the forces of government are scattered. Moral superiority, finally, is vital; and the announcement of daily, even hourly, successes has great importance in depressing the enemy, in consolidating the offensive and in keeping the masses on your side. Surrounding all must be the ultimate perspective of audacity without which supreme success is impossible. Revolution, therefore, may be said, from the angle of socialism, to depend on three conditions: (1) It must be not a conspiracy nor a party move but the rise of the revolutionary working class. (2) It must have the masses on its side and must therefore build its appeal on their most urgent demands. (3) It must break out at the crux of rising activity among the friends of revolutionary change and at the moment of greatest indecision on the part of the enemy.

The working class is thus brought to power. The communist insisted that the preservation of power involves the dictatorship of the proletariat. It is essential to crush out opposition and to shatter the institutions of the defeated regime. Revolution is war and until there is complete acquiescence in the victor's terms the methods of war alone are suitable to it. "The enemy," said Lev (Leon) Trotski, "must be made harmless, and this means he must, in wartime, be destroyed." For, willing the end, the communist cannot wipe his hands of the means. Hesitation, weakness, pity, a false worship of democracy, only stimulate the forces of counterrevolution and prevent the consolidation of the new regime. The dictatorship is exercised by the Communist party because: (1) its members have been tried and can be trusted; and (2) they represent the real will of the workers that has been suppressed and obscured by capitalism. The dictatorship is a trust for the revolution that, in its turn, is a fulfillment of the mission to which the working class is historically called.

Violence therefore wins the revolution and dictatorship consolidates it. The transition to socialism is accomplished in two stages. In the first, the oppression of classes disappears, and with it, the state, which is merely the instrument of class oppression. The proletariat seizes power and by using it to destroy the class structure of society ceases to be a proletariat. The instruments of production are socialized. But coercive power is still necessary because the minds and hearts of men are not easily accustomed to the new regime. Government therefore continues, though growing acceptance of the new society means growing democratization of social processes. This, however, does not mean parliamentarianism, which is merely a bourgeois form of government, but the soviet system which combines the advantages of the territorial with the virtues of producers' representation. Formal democracy is replaced in the first stage by what the communist called "the revolutionary dynamic of living forces," which means that all elements in society except the working class are deliberately excluded from power. Great industrial enterprises, the banks, the means of communication and the large landed estates must be confiscated. Wholesale commerce should be nationalized; foreign trade must become a government monopoly. The means of propaganda, the press and education, must be confined to working-class direction. Small business may be left untouched, because it is futile to think that communism can be established at a stroke. Measures must be taken to associate intellectual technicians with the new order and to neutralize the

peasant classes by organizing the poorer, while repressing sternly the antagonism of the richer peasants. So, *mutatis mutandis*, with the poorer bourgeoisie of the towns.

Communism cannot be said to have had any clear view of the ultimate social order it proposed to establish. It took over from Marx phrases like the demand "from each according to his powers, to each according to his needs," and the "administration of things instead of the administration of persons." But it was mainly occupied with the immediate revolutionary task. It conceived, moreover, of the revolution thus established as a world revolution made in each country on conditions similar to those in Russia. For this purpose the formation of a world Communist party rigorously directed from a single centre and sternly disciplined from above was fundamental. To advance the revolution advantage must be taken of national, racial and economic discontent where these exist; but propaganda in relation to them must seek always to move them to significance in terms of the class war. Union should be sought with the reformist working-class parties, but always on the understanding that they are bound to fail and that if they arrive in power the communist must separate from them and fight them. Finally, it is to be noted that communism regarded religion as a capitalist instrument used as an anodyne for the workers and sought wherever possible to destroy its influence.

**Revolutionary Additions.**—Lenin seized power in war-devastated Russia in Nov. 1917, over-throwing the short-lived democratic revolutionary regime established through the collapse of tsarism in March 1917. During World War I he assumed an intransigent attitude against any form of "patriotism" and wished to transform the national war into a class war. He returned to Russia in April 1917; under his leadership the left wing of the Social Democratic party, the only group with strict discipline and definite purpose, emerged in the general chaos to channel the amorphous and leaderless discontent of the masses. The group established its dictatorship as a "dictatorship of the proletariat," abolished the newly won political and civil liberties in Russia, renamed the party "Communist party," and, because of the leadership of Lenin and Trotsky, kept itself in power against great initial odds.

According to Leninism, political, economic and intellectual life must be regulated by the "proletariat's advance guard," the party, because the people and even large parts of the proletariat, educated in the pre-Communist era, are unable to realize the new order. The masses have to be guided in a strictly regimented fashion toward participation in the new order. Communism believes that "true" democracy cannot be realized in any non-Communist society because of the economic exploitation by private elements of society (the possibility of economic exploitation by the state itself is not considered), and that parliamentary democracy only veils the control of society by capitalists. Therefore the building of the future perfect society proceeds under an autocracy, unbound by any law or ethical consideration of the "bourgeois" age. To this future, the coming of which is assured under omniscient leadership, the happiness of the present generations and the rights of the individuals are sacrificed. Marxism and Leninism originally expected that with the triumph of the proletariat the state which Marx defined as an organ of class rule would "wither away" because class conflicts would come to an end. Communist rule in Russia, however, resulted in an ever increased power of the state apparatus. The Communist dictatorship created the first and most perfect example of the totalitarian state in which no sphere of individual life was allowed to remain outside its all-inclusive grip. In the effort to create a "true" democracy, terror was employed without hesitation; humanitarian considerations and individual rights were disregarded; and the assumption of the class character of all intellectual and moral life led to a relativization of the standards of truth and of ethics. On the other hand, communism gained much of its power over human minds by the "scientific" prediction and promise of establishing social justice and perpetual peace after the liquidation of all its actual or potential adversaries.

Though the final goal was never lost sight of, communism passed through several phases of adaptation on this road. In

1919 Lenin had founded the communist or third international, but it proved unable to make any serious progress outside Russia before World War II, and the several Communist parties existing abroad became instrumental to the policy of the Communist state in Russia. (See INTERNATIONAL, THE.) With the temporary abandonment of an immediate world revolution, Lenin replaced the policy of "war communism" by the "new economic policy" (NEP) in March 1921. It represented a compromise between nationalized and private economy, but in 1928 a renewed drive for the "realization of socialism" in the Soviet Union set in under the leadership of Stalin, Lenin's successor. This speedy drive toward socialism called for advanced planning in all branches of the economic and cultural life of the country. Under the form of five-year plans, the natural resources of the country were successfully exploited and large-scale heavy industry was built up; individual farms were collectivized and machinery and more efficient methods of cultivation were introduced into agriculture; illiteracy was fought and education used for the re-education of the soviet citizen. The deep-seated conviction of an "inevitable" clash between Communist Russia, the bearer of the true faith and of the only valid social order, and the outside world led to emphasis being placed on a "war economy" and the subordination of all activities to the need of "defense."

After having abandoned the hope for revolution in Europe, communism concentrated for some years upon the revolutionary movements in the orient, especially in China which by its geographic position and its potential strength became the centre of Communist interests and activities in Asia. But hopes there were temporarily frustrated by Chiang Kai-shek in 1927.

**Tactical Change.**—The growth of aggressive fascism in Germany and Japan during the 1930s brought about a complete tactical change in Communist policy. The U.S.S.R. joined the League of Nations in 1934 and stressed its willingness to co-operate with democratic forces against fascism. Communists outside Russia declared themselves ready to form a "popular front" with the liberals and socialists whom they had formerly vehemently combated and abused. After 1935 much greater stress was put on the U.S.S.R. as the only genuine leader and representative of communism. Communism was regarded as a new form in which the historical traditions and aspirations of the Russian empire and the Russian people were vitalized. The flexibility of Communist policy was perhaps enhanced by the ruthless "purges" of 1936-38, in which Stalin eliminated all those persons, many of them among the oldest and most renowned Communists and closest collaborators of Lenin, who could endanger his leadership. In this process several hundred thousand leading personalities of the political, economic and military life of the U.S.S.R. were liquidated as "traitors" or "enemies of the people."

This flexibility in policy, though not in Communist principles and goals, showed itself in the sudden change of the "general line" in Aug. 1939 when the Soviet Union reversed its policy of collaboration with the democracies in the struggle against fascism and lined up with aggressive fascism, which Communists had proclaimed until then the mortal enemy of the proletariat, of peace and of progress. In Aug. 1939 Stalin concluded a treaty of friendship and nonaggression with Adolf Hitler and thereby gave the green light to German aggression which unleashed World War II. The U.S.S.R. participated with Germany in the destruction and partition of Poland. In April 1941 Stalin concluded a five-year treaty of friendship and nonaggression with Japan which, however, he broke four years later. During the first two years of World War II Communists everywhere vied with the fascists in directing their attacks against democracy or, as the fascists called it, "plutodemocracy." They regarded the cause of World War II to be not German aggression but British and French imperialism. They tried to sabotage the intellectual and material defense program of the democracies against fascist aggression. The candidacy of Franklin D. Roosevelt for president of the United States in 1940 was violently opposed as that of a "warmonger" in the service of U.S. big business. The attitude of sympathy toward fascist Germany changed naturally with the unprovoked German attack on the U.S.S.R. on June 22, 1941.

For the next four years all the forces of communism were concentrated on winning the war against Germany. To that purpose an uneasy alliance with the democracies was maintained, without the Communists ever losing sight of their ultimate political goal which divided them sharply from their wartime allies.

As an apparent concession to the wartime allies, the Communist international was dissolved on May 22, 1943. Yet the Communist parties everywhere continued to follow without criticism or hesitation the party line as laid down by the Russian Communist leaders. The cause of the Soviet Union was identified with the Communist cause; loyalty to the U.S.S.R. and loyalty to communism were one. This attitude continued in spite of the change from the original proletarianism of Lenin to the emphasis on Russian traditions carried through by Stalin in all fields after 1940. He restored the titles and splendours of the old regime with its ornate uniforms and its militarized bureaucracy, even in the most civilian departments. Coeducation was abolished in all higher schools, to take into account the different nature of the two sexes; the boys were trained for a stern soldier's life while the girls were educated for motherhood. A new stress was put upon family and authority. Stalin himself was regarded more and more as the object of a Byzantine adulation, surpassing even that accorded to the tsars of the past. He was regarded no longer as the autocratic leader of one empire, as Ivan the Terrible and Hitler were, but was glorified as the infallible leader of all peoples, of the whole of "progressive" mankind, the omniscient teacher of all sciences and all arts.

**Postwar Revision.**—At the end of World War II this stress on the Russian cultural past—which was now exalted as superior in its nature and in its achievements to all other civilizations—was combined with a new emphasis on the purity of the Leninist-Stalinist doctrine. A relentless war was waged upon all "deviations." To that purpose, Communist Russia was more strictly isolated by its rulers from any contact with the outside world than had ever been attempted before in the traditionally closed society of tsarist Russia. This policy of self-isolation was accompanied by violent campaigns against what was called "homeless cosmopolitanism" and "belittling" of the leadership of the U.S.S.R. in all fields of culture, a sin apparently committed by some Soviet critics and scientists who continued to indulge in the crime of "toadying" before the west.

The new development of communism after World War II showed two opposite faces—a completely closed society in Russia, protected from every contact with the outside world, and, at the same time, the resumption of the original world-wide revolutionary drive. Summing up Lenin's testament to the party, Stalin had declared after the leader's death in Jan. 1924: "Lenin never regarded the republic of soviets as an end in itself. He always regarded it as a necessary link for strengthening the revolutionary movements in the lands of the west and the east, as a necessary link for facilitating the victory of toilers of the whole world over capital. Lenin knew that only such an interpretation is the correct one, not only from the international point of view but also from the point of view of preserving the republic of soviets itself." Twenty-five years later, after the victories of the Russian army and of the Communist diplomacy in Europe and Asia, Soviet communism felt a new aggressive and dynamic vitality. It saw itself as the irresistible vanguard of an immense forward movement which the military and economic disintegration of Europe and Asia seemed to favour. Nevertheless, Communists nowhere gained a majority in free elections, not even in territories which were under the control of Soviet armed forces or within the orbit of Soviet diplomacy. The weight of the continuous Communist offensive was mainly sustained not by the mighty Communist propaganda machine and its outwardly attractive slogans and appealing oversimplifications but by the power and preparedness of the Soviet army. Even in China and Korea Communist successes were due to the existence and strength of Communist armies, and not primarily to Communist programs or policies. In Italy and France, where such armies were not in existence, the numerically strong Communist parties with their financial and intellectual backing were unable to score any lasting success.

In Sept. 1947 representatives of nine Communist parties (U.S.S.R., France, Italy, Poland, Yugoslavia, Bulgaria, Rumania, Hungary and Czechoslovakia) met in Poland to establish the Communist Information bureau (Cominform). Belgrade, Yugo., was selected as its seat; a vote of confidence by international communism for the Yugoslav Communists and their leader Tito was seen in this choice. The Cominform asked all those in favour of "democracy and peace" to close ranks around it against the threat of "reactionary and imperialist" aggression led by the United States. The Communist-dominated countries outside the Soviet Union were organized as "people's democracies." Though the Soviet Union always stressed their sovereignty, they were assimilated more and more completely into the pattern of life in the Soviet Union. The often propagated thesis that the various Communist parties were independent and could follow a different and more moderate line than that taken by Russian communism, was temporarily ended when in 1948 the Soviet Union and the Cominform attacked violently the Yugoslav Communists for not submitting completely to the directives coming from Moscow.

The Cominform revealed itself as the supreme directive and centralizing organ in the world-wide struggle for Communist victory. Like the Comintern before, it was unreservedly under the control of the Soviet party, and the slightest deviation from the Moscow line was mercilessly fought as treason. The Yugoslav Communists were excluded from the Cominform and its seat transferred to Bucharest, Rum.

The world-wide implications of Communist policy were stressed by Georgi Dimitrov, the famous Bulgarian Communist leader, who wrote on Dec. 18, 1948: "It should not be forgotten that—in spite of the fact that the Communist International does not exist—all Communist parties in the world form one single Communist front, under the direction of the most powerful and most experienced Communist party, the party of Lenin and Stalin; that all Communist parties have one common scientific theory as a guide to their actions—Marxism-Leninism; and that all Communist parties have one leader and teacher, recognized by all—Comrade Stalin." Commemorating the Communist seizure of power in Prague, Czech., of Feb. 1948, the Communist speaker of the Czechoslovak parliament, Oldřich John, declared on Feb. 22, 1949: "February 1948 was not a decision concerning only our country, but the whole world. At a decisive moment and at a decisive key position in Europe we achieved a critical shift of the forces of the world. . . . Our February . . . belongs to the working class of the whole world which is expecting its February. It will have it."

The declaration introducing the first constitution of 1923 of the newly formed Union of Soviet Socialist Republics stated that since the formation of the Soviet Union the countries of the world had split into two camps, the camp of capitalism, with national oppression, imperialist brutality and wars; and the camp of socialism, with peace and harmonious collaboration. Thirty years later, the Communists were more than ever convinced that history had put on the order of the day the final and total victory of communism. This victory, according to Communist doctrine, held with religious fervour would create a world of one faith and one leadership which would assure the peace and security for the Soviet Union and the certainty of salvation for the whole of mankind. The shift of power following World War II made, in the eyes of the Communists, the United States the leader in the opposite camp of democracy, of that western way of life which, according to Soviet communism, had been doomed by its own inner contradictions and by the irresistible march of history.

**Khrushchev.**—Stalin's death on March 5, 1953, ended the era of inflexible personal dictatorship over every detail within the Soviet orbit. After a brief interval of readjustment, Nikita Sergeevich Khrushchev (q.v.) emerged as successor to Stalin's office, but not to his policies. He introduced flexibility, abandoning Stalin's isolation from his people and the world. In May 1955 Khrushchev reversed Stalin's rejection of Tito for assuming an independent attitude. In Feb. 1956 at the 20th Communist party congress he denounced Stalin's assumption of omniscience, not only political but literary, artistic, scientific and military, as the "cult of the individual." Khrushchev's new approach, coupled with Mao

Tse-tung's unwillingness in China to accept from younger men the direction he had tolerated from Stalin as a senior with long experience, set off a chain of events undermining the previously monolithic character of Communist leadership.

Polish Communists, emboldened by the new flexibility and forced to compromise by a population embittered by Stalin's program of speedy adoption of Soviet patterns, restored Wladyslaw Gomulka to the leadership from which Stalin had evicted him. Khrushchev capitulated after Soviet threats proved unavailing and accepted in Oct. 1956 the right of Polish Communists to devise their own path so long as they moved toward socialization and supported Soviet foreign policy. Chinese Communists, wishing greater freedom of action, supported the Poles. Hungarians misread the signs and revolted, not only denouncing Moscow's dictatorship of their policy but withdrawing from the 1955 Moscow-oriented Warsaw pact of military alliance (*see* WARSAW TREATY ORGANIZATION).

Faced with armed rebellion, Khrushchev quelled the revolution with Soviet troops and re-established the Hungarian Communist party's power, but under a less fanatical leader, János Kádár. Hungary was permitted to satisfy demands for consumer goods but not for worker control of factories or intellectual freedom. Tito's sympathy for the Hungarian renegade Communists and his granting of brief asylum to Imre Nagy, moderate Communist chief of government during the revolutionary days, aroused Khrushchev's anger.

To overcome emerging centrifugal forces, in Nov. 1957 Khrushchev summoned to Moscow Communist party leaders from states where they ruled. The meeting issued a declaration of unity under leadership of the Soviet Union's party in furtherance of "proletarian internationalism." Tito alone refused to sign, bringing upon himself subsequently renewed denunciation as a revisionist of Marxism; the Chinese Communists were even more vitriolic in the attack than were the Soviet Communists. In spite of lip service to Soviet leadership Chinese Communists asserted their right to introduce agricultural communes contrary to Soviet advice and to share in foreign policy decisions, even to having a major voice in those decisions relating to Asia.

The periodic conferences agreed upon in 1957 "to share experiences, to study each other's views and attitudes, and to concert action in the joint struggle for common goals" occurred only once thereafter, in 1960. Yugoslav Communists were denounced as "following a policy of right-wing opportunism which reflects bourgeois ideology in theory and practice," but the denunciation was soon forgotten by all but the Chinese and Albanian Communists. Khrushchev even traveled to Belgrade to renew friendships in the face of mounting hostility from the Chinese.

**Sino-Soviet Denunciation.**—Chinese Communists published in mid-1963 correspondence with the Soviet Communist party attacking the latter's 1961 program for both its domestic and foreign policy statements. The Chinese said no Marxist-oriented state could outlive the class struggle and become a "state of the whole people," as the program proclaimed, and that a policy of "peaceful coexistence" in foreign affairs could not advance revolution in developing areas. The Chinese demanded revolutionary militancy both at home and abroad, accusing their Soviet counterparts of "opening the gates to capitalism."

Communists in other countries were pressed to take sides in an increasingly vitriolic exchange of epithets. The Rumanians chose the occasion to show their independence in 1964 by asserting their neutrality. They even declared economic independence of the Council of Mutual Economic Assistance (COMECON) to which European Communist-controlled states and Mongolia belonged. The Rumanians refused to accept joint plans of the organization calling for a largely agricultural contribution from their country. They wanted to industrialize and increase trade with the West.

In Aug. 1964 the long-term leader of the Italian Communist party, Palmiro Togliatti, died, leaving a political testament accusing Moscow of heavy-handed treatment of world communism and rejecting re-creation of a new centrally controlled Communist world organization. The French Communists announced that their

policies would be based on French conditions only, and not on any world Communist view.

Khrushchev was voted out of power by his colleagues in the Central Committee of the Communist Party of the Soviet Union in Oct. 1964. Opposition to him was based largely on his domestic policies, but criticism was also levelled at his inability to resolve the quarrel with the Chinese. His successors, Leonid I. Brezhnev and Aleksei Kosygin, attempted to restore unity of Communist parties, inviting 26 to Moscow to discuss matters. Only 19 accepted. Those refusing represented populations totalling half the Communist-dominated world, the most important absentee being the Chinese Communists. The Chinese in refusing to attend charged that the "Soviet Government is subservient to United States Imperialism." Evidently Khrushchev's successors were to have no more success at healing the gap than he had experienced. No unity Congress was held.

The leaders in Moscow tried again in April 1966, using the Soviet Communist party's 23rd Congress as the occasion to invite guests. The Chinese again declined the invitation, telling the Soviet party, "You have even aligned yourself with United States Imperialism and the reactionaries of all countries in a vain attempt to establish a Holy Alliance against China." Parties in Albania, Japan and New Zealand agreed. But the tide was beginning to turn against the Chinese.

**Chinese Defeats.**—In Oct. 1965 Indonesian Communists, acting in concert with Chinese Communists, attempted a coup, killing most of the high command of the Indonesian army. One escaped to lead a counterattack which restored order but toppled many of the former ministers of President Sukarno's government. Thousands of Indonesian Communists were hunted down and killed by enraged villagers, and student organizations denounced collaboration with Communists. Peking's policy of violence had failed, and Communists of many lands turned to accept the Soviet policy of "peaceful coexistence" which shuns outright military action, focusing on ideological struggle supported by economic aid and education in Marxist principles.

Significantly, North Korean and North Vietnam Communists who had previously supported the Peking policy sent delegates to the Soviet Congress of 1966. Thereafter other Communist parties favourable to Peking changed sides, the most notable being the Japanese. Emboldened by this success, Soviet Communists began to move toward exclusion of Chinese Communists from the "commonwealth," seeking support at the meetings of the Bulgarian Communist party in Nov. 1966. This was not forthcoming, largely because the Rumanian and Yugoslav parties were reluctant to make a move that could have been interpreted as restoring criteria for membership in the "commonwealth" which might limit their own independence in the future.

Communism in the late 1960s was a movement with many variations of thought held together by a common purpose to remake the world without the capitalist system, but divided sharply on how to do it. The split between the two giants of the movement on tactical lines was exacerbated by historic animosity: the Chinese even claiming return of some 500,000 sq. mi. of territory taken from the Chinese empire by the Russian tsars through treaties forced on a China defeated in various Sino-Russian wars.

**COMMUNISM, PRIMITIVE.** The concept of primitive communism was essentially a product of the evolutionary theories

of the mid-19th century, according to which the early history of mankind was characterized by a stage of society radically opposite to the modern western type. Hence it was thought that early man held his property, including his land, in common, and that some kinds of relations between persons, especially sex relations, were governed by no rule within the group. To such primitive communism, it was held, there succeeded various more limited forms of property holding and marriage. In the attempt to give reality to such evolutionary schemes, the institutions of certain contemporary primitive peoples were identified as having this communistic character or as being at a stage barely removed therefrom. W. H. R. Rivers, for example, held that in Melanesia there was a fairly definite association of two kinds of communism, in ownership of property and in sexual association. He interpreted clan rights over land in Ambrym as excluding all individual ownership; he thought that at Raga communistic ownership still persisted for canoes; he looked upon the Fijian custom of *kerekere* (which allows a person to appropriate the property of others in the category of maternal uncle) as fairly definite evidence of communism; and he regarded the system of prenuptial sex relations in Eddystone Island (which had a very strict code for married people) as "a state of organized communism which may be the survival of an earlier state in which this communism also existed after marriage" (*Social Organization* [1924]; copyright Routledge & Kegan Paul Ltd., London). Rivers, however, did not regard organized sexual communism as the earliest stage in the evolution of human society but as growing out of a condition in which the institution of family was recognized. E. Durkheim generalized such views in terms of his theory of primitive collectivity, arguing that communism of property was a necessary product of the special cohesion in primitive society which marked the absorption of the individual into the group.

The question of the validity of the concept of primitive communism, which did not receive much support from developments in anthropology in the 20th century, was revived by Soviet theorists. Some, such as P. Kushner and P. F. Preobrazhenski, held that such theories were based upon insufficient knowledge of primitive conditions, but others, such as N. M. Matorin and E. Kagarov, argued that ethnographic data had confirmed it beyond doubt. Basing their arguments largely on the views of Karl Marx and Friedrich Engels, who in turn had drawn upon the work of L. H. Morgan, they regarded the postulate of primitive communism as an augury for the future—according to the idea expressed by Marx that the new system which modern society is approaching will be the re-emergence of the archaic social type in the highest form. Most Soviet ethnographers seem to adhere to Morgan's evolutionary scheme and uphold the collective communal-clan character of early human economy as universal.

Leaving aside political implications of the concept, modern anthropology found it inadequate as a matter of ethnographic fact. The essential features of a communist condition of society are: a common ownership of the means of production, labour contributed according to ability and the product shared according to the needs of the members of the society. This is antithetical to a system of private control of productive resources. The evidence from a wide comparative study of primitive economic systems does indicate a marked communal interest in rights over property, especially over the basic productive resources: in an agricultural community the rights of any individual over land are subject to the overriding rights of the kin group of which he is a member; in a pastoral community he may seem to have no separable rights to land at all. But the system of rights is complex. All members of the community do not share alike but have their rights to ownership closely defined by rules of kinship and residence. Use of land, water, crops, cattle and canoes is governed by recognition of the primary title of some kin group or even of some individual, and other individuals base their claims upon defined kin or other status rights—as, for instance, being a sister's son. In an Australian aboriginal community the game that is killed must be shared among other members of the hunter's group, and this is not done on the basis of need of the individuals concerned but of their entitlement according to a complex set of rights and duties in

virtue of their kinship to the hunter. So, even in the simplest primitive communities the principles of ownership involve complex patterns of individual rights, not undifferentiated community control and sharing according to need. When careful analysis is made of the concrete system of rights and obligations in any primitive society, modern anthropologists agree with B. Malinowski, O. Leroy and R. Thurnwald that, while these cannot be adequately described exclusively in terms of individualism, the concept of communism is equally inadequate. Primitive institutions of sex relations and marriage also exhibit analogous complex systems of rights, which frequently differ from those in modern western institutions but to which the label primitive communism is quite inapplicable.

If the material from modern primitive communities cannot be interpreted as evidence of extant primitive communism, neither does it allow modern institutions to be postulated as survivals of an earlier communistic state. Primitive institutions are intelligible in the context of other social, economic and political circumstances immediately associated with them; reference to some hypothetical past is not necessary. The argument for primitive communism as an early stage in human history remains in the realm of speculation. See also LABOUR, PRIMITIVE; LAND TENURE, PRIMITIVE; MARRIAGE, PRIMITIVE.

**COMMUNIST INTERNATIONAL:** see INTERNATIONAL THE.

**COMMUNIST PARTIES**, groups organized for political action designed to inaugurate a worldwide communist social order by seizing and exploiting political power and economic resources in conformity with a pattern introduced in Russia in 1917 (see COMMUNISM). Outside Russia, Communist Party leadership followed directions given by Russian initiators for 30 years until Yugoslav Communists demanded autonomy in decision making in 1948 and refused to accept the Union of Soviet Socialist Republics as the "fatherland." Other Communist parties denounced the Yugoslav party as "revisionist," but later showed degrees of independence.

**General Characteristics.**—Characteristic of all Communist parties, including Yugoslavia's, were strongly held beliefs traced in origin to the doctrines of Karl Marx and Friedrich Engels (*qq.v.*) but modified and developed by their successors. These were belief in the superior productivity of a state-planned economic system over private enterprise; the necessity of state ownership of productive resources to prevent exercise of economically derived political power by private individuals or corporations; the organization of land use by communities; the propagation of atheism; the impossibility of obtaining power except by violence; the monopolization of political power after victory by a leadership corps composed of a relatively few disciplined, politically active persons dedicated to the achievement of communism; and the preliminary favouring of the mass over the individual as essential to ultimate fulfillment of the individual. Where Communists had not achieved power or where power, although achieved, had not become absolute, goals were often compromised, as in Poland in 1956, but basic aims were reasserted when possible.

Before seizure of power and briefly thereafter Communist parties sought influence by attracting disgruntled social elements, notably ethnic minorities and the poor, to whom successful members of the prerevolutionary society were depicted as exploiters. In extension of this tactic to the international scene powerful states blocking realization of Communist policies were castigated as "imperialist," notably France, Great Britain, and Germany between the world wars and the United States thereafter. Playing upon the universal craving for peace, Communist parties

sought political advantage by claiming for their scheme of world order the role of "peace program" and calling their opponents "warmongers."

To advance their cause in states where power could not yet be seized, Communists sought membership in mass organizations, notably labour unions, social and cultural associations, military forces, and the government bureaucracy, attempting to weaken the society from within, as in Czechoslovakia in 1948. Hoping to prevent such infiltration, governments of 38 independent states and semi-independent colonial areas had outlawed Communist parties by law or by practice by 1960, arguing that they were not true political parties pledged to function within a parliamentary democracy but were an instrument of revolution directed from Moscow.

**Contrast With Socialist Parties.**—Communist parties differed from Socialist parties in aims and organization, although Communist parties had often emerged originally as left wings of Socialist parties, and although both sometimes participated after the initial organizational split in coalitions to oppose rightist parties in parliaments. While both espoused state economic planning and held state ownership necessary to planning, Socialists believed it necessary to seize only "commanding heights"—banking, communications, key heavy industry—in contrast to Communist doctrine that all economic enterprises employing labour must be state-owned. After 1958 German and British Socialists accentuated the contrast by questioning even the desirability of state ownership of key industry provided state control was assured.

Socialists, like Communists, professed working-class orientation, but Socialist parties opened membership to all. Communist parties admitted relatively few, except in countries where competition with Socialists dictated competitive membership tactics, as in Italy after World War II. Socialists thought achievement of goals possible through parliamentary procedures: Communists denied the possibility and sought power through violent revolution, although where such tactics attracted little support, conventional election campaigns were conducted until violent seizure of power seemed feasible.

Socialists left religious belief to the individual's conscience: Communists required members to espouse atheism. Communists foresaw ultimate social organization without institutionalized force to maintain order, force being unnecessary when human wants were satisfied and self-discipline learned. Socialists considered this aim Utopian, if not a mask for contemporary police regimentation. (See also SOCIALISM.)

**Origin.**—Industrial unrest at the end of the 19th century brought forth a small vigorous Marxist movement in the cities of Russia. Although industry developed so slowly that there were by 1890 only an estimated 2,400,000 industrial workers in the Russian Empire, the influence of the more advanced working classes of Western Europe was noticeable. Russian *émigrés* such as Georgi Valentinovich Plekhanov served as the funnel through which Marxist literature and concepts were smuggled from abroad to Russian groups operating at home. Most Russian workmen's groups adopted the concepts of Social Democratic thought represented by the Second International, which had been formed by Western European workmen in 1889. (See INTERNATIONAL, THE.) The first important split with the Second International's approach to seeking power by peaceful parliamentary means came in 1895 with the organization in St. Petersburg of the League of Struggle for the Emancipation of the Working Class. One of its influential sponsors was Vladimir Ilyich Ulyanov, known as Lenin (*q.v.*), who was later to become the principal figure of the Russian Revolution.

Similar leagues were formed in other cities and these joined with a left-wing Jewish organization called the Bund to send delegates to a meeting in Minsk in 1898. At this meeting was formed the Russian Social-Democratic Labour Party (RSDLP), from which the Communist Party dates its official beginning. Delegates issued a manifesto calling for a struggle against autocracy and capitalism until the complete victory of socialism. After the meeting most of the party leaders were arrested and the work

of the party was reduced to activity in the local underground organizations.

The great industrial depression of 1899–1900 in Europe spread to Russia at the beginning of the 20th century, resulting in bankruptcy and unemployment. Street demonstrations and strikes appeared. Lenin, who had been exiled to Siberia in 1897, returned to take part in reorganization of party work in the fertile soil of industrial unrest. The Russian Social-Democratic Labour Party was re-formed at a congress of delegates, which met in Brussels, Belg., in 1903 to avoid arrest at home. Police observation was such that this congress transferred its session to London to complete the work of organization. At this congress appeared the great split between left and right wings which plagued party unity for years.

The left wing, supported by Lenin's adherents, called for a militant, disciplined, centralized party, which would be proletarian in composition. It urged a clear line of demarcation between nonparty members, who might sympathize with party aims, and party members, who would be required to recognize the party program, pay dues, enter one of the party organizations, and work actively. The right wing, to which Lev Davydovich Bronstein, known as Leon (Lev) Trotsky (*q.v.*), adhered, urged a broader membership base, requiring only that a member recognize the program and render aid. The right wing's conception was adopted at this time. The right- and left-wing factions split again later in the congress. Some right-wing elements who had disagreed with the conduct of affairs withdrew so that in the vote for members of the Central Committee and the editorial board of the party press, the left wing became the majority. It was given the name Bolshevik, signifying this fact. The minority right wing was called Menshevik in turn. These labels were carried over after, even though power passed back and forth from time to time. The split between the factions became so great that in 1905 they met separately. The Menshevik faction met in Geneva, Switz. The Bolshevik faction, meeting in London and led by Lenin in person, adopted his concept of membership. This remained the rule of the party.

Although there were subsequent periods in which the Mensheviks and Bolsheviks acted in concert, the split continued up to the Revolution. After the Revolution some Menshevik leaders transferred their allegiance to the Bolshevik cause. The Menshevik faction disappeared as a political unit in the U.S.S.R.

The party named itself the Russian Communist Party in March 1918. It changed its name again in 1924 to All-Union Communist Party (Bolshevik) to dramatize its place within the federation. In 1952 it became the Communist Party of the Soviet Union.

**External Influence.**—The Russian Revolution, coincident with worldwide popular discouragement and regional impoverishment, stimulated creation of Communist parties in many lands, sometimes on a base of a prewar, Marxist-oriented group paralleling that of Russia. A Swedish group created a Communist Party in 1917, and similar parties appeared in defeated Germany, Austria, and Hungary after World War I and also in Greece, Yugoslavia, Poland, Bulgaria, Argentina, Mexico, Denmark, and the United States. Thereafter the movement gained recruits, following Lenin's organization in Russia of the Communist International in 1919 to prepare leadership for eventual worldwide revolution and to support the policies of his fledgling government.

In 1920 Communist parties were founded in France, the United Kingdom, Turkey, Australia, Iran, the Dutch East Indies, and Uruguay. In 1921 they appeared in Italy, Spain, Brazil, Chile, India, Switzerland, Rumania, Czechoslovakia, China, and Mongolia; in 1922 in Japan and Norway; in 1924 in New Zealand; in 1925 in Cuba and Korea; in 1928 in Ecuador and Paraguay; in 1930 in Syria-Lebanon, Costa Rica, and Indochina; in 1934 in Algeria (previously under the French party); in 1943 in Ceylon and Morocco (previously under the French party); in 1946 in the German Democratic Republic; in 1948 in Israel; in 1949 in Bolivia; and in 1951 in Nepal and Vietnam.

Moscow claimed 33,000,000 members for Communist parties in 83 countries in 1959. Foreign experts believed these figures to be approximately accurate and estimated that 85% of the Com-

munists were in the Sino-Soviet bloc. The 1965 estimates of membership (made by the U.S. Department of State) were China 18,500,000; the U.S.S.R. 12,000,000; Italy 1,350,000; Poland 1,725,000; German Democratic Republic 1,610,679; Czechoslovakia 1,684,416; Korea 1,600,000; Hungary 540,000; Vietnam 700,000; Yugoslavia 1,030,041; France 280,000; and Bulgaria 550,038.

Between the two world wars, Communist success outside the U.S.S.R. was greatest in continental Europe and China, and weakest in Anglo-Saxon, Scandinavian, Islamic, southeast Asian, Latin-American, and African countries. Various factors, including alternative outlets for discontent, satisfactory wages and working conditions, strongly held religious beliefs, and insulation from outside influence because of illiteracy or sealed frontiers, accounted for Communist failure to penetrate these areas.

**Great Britain.**—British workers, although class conscious, supported the Fabian socialism of the Labour Party so that Communists were without effective influence in Britain. Communists at maximum strength held two parliamentary seats in 1945; they lost them in 1950 and remained without representation in 1959. In 1966 interest ebbed further. Fifty-seven Communist candidates forfeited deposits. Similar lack of interest existed in Canada, Australia, and New Zealand.

**Germany.**—German Communists, to whom Lenin looked for primary foreign support, failed to gain control of the Constituent Assembly in 1919. Their power waned after the assassination in 1919 of their leaders, Rosa Luxemburg and Karl Liebknecht (*q.v.*), not to be regained until economic disintegration increased disillusion, evidenced by an increase of *Reichstag* representation from 4 seats in 1920 to 62 in 1924, 77 in 1930, and 81 in 1933 when 12% of the popular vote was polled. Shortly thereafter Adolf Hitler suppressed the party, although it remained underground to reemerge with the military defeat and partition of Germany in 1945. With Soviet support Communists became the masters in Eastern Germany. In Western Germany the party was declared illegal and the declaration was upheld by the constitutional court in 1954.

**Italy.**—Italian Communists won 13 parliamentary seats in 1921 but were suppressed by Benito Mussolini after 1924, not to reappear until after Italian military defeat in World War II. Their Moscow-trained leader, Palmiro Togliatti, chose to work, until his death in 1964, in a leftist popular front which polled 40% of the vote in 1948. In 1966, the party split under pressure of the rift between Soviet and Chinese Communists, and its Socialist allies turned away, leaving it divided and isolated.

**France.**—French Communists under Maurice Thorez joined in 1934 with Socialists and Radical Socialists to create a leftist popular front to oppose rightists. This grouping won the 1936 elections to make the Socialist Léon Blum premier for a year; the Communists refused ministerial portfolios but promised cooperation and parliamentary support. On Blum's fall, Radical Socialist leadership eliminated the Communists from the coalition.

During Hitler's occupation of France, but only after his attack upon the U.S.S.R. in 1941, French Communists participated vigorously in the resistance. Playing upon the goodwill thus won, the Communist Party emerged in liberated France as one of three major parties, evidencing power to make or break Socialist and Popular Republican governments by withholding votes. Ministerial posts were held occasionally in 1957, but after the electoral victory of Gen. Charles de Gaulle's party in 1958 and reorganization of the electoral system to exclude proportional representation, Communist strength dropped to ten seats in 1960. Further loss of prestige occurred in 1966, after De Gaulle was received enthusiastically in Moscow for his antiwar policy.

**China.**—The Chinese Communist Party was organized in 1921 by intellectuals led by Ch'en Tu-hsiu (*q.v.*) and aided by Russian advisers, assuring incorporation of the Russian party's organizational principles in the rules of 1924. Seeing no hope of independent influence, Communists cooperated with Sun Yat-sen's Kuomintang party, but on his death in 1925 opposition from Sun's right-wing heirs developed into an open break in 1927. Under Chiang Kai-shek's leadership the Kuomintang formally outlawed

the Communist Party. Mao Tse-tung (*q.v.*), one of the 1921 founders, withdrew to interior China to establish a rural soviet, the basis for his subsequent rise to power as unquestioned leader in 1935.

Mao, concluding that Communist hegemony was impossible in the cities, developed the tactic "to encircle and subsequently to seize the cities occupied by the counterrevolution, by means of armed, revolutionary rural districts," thus providing the basis for the Chinese innovation of "agrarian Communism." As Communist military strength grew rurally, the Kuomintang attempted annihilation campaigns but without success until 1934 when they forced the Communists to retreat on the historic "Long March" to northern Shensi. From there Mao launched the Anti-Japanese National United Front in 1935, designed to win popular support.

Mao effectively aroused the commander of the Manchurian army against Chiang's anti-Communist policy in the face of Japanese aggression. Chiang was kidnapped by the Manchurians in 1936 but his life was spared, reputedly on Moscow's intervention and on condition of a new truce between the Kuomintang and the Communists. Although the Red Army was nominally incorporated in Chiang's army, it was actually left intact, and an emissary was sent to Chiang's capital for liaison. During the Chino-Japanese War, 1937-45, both sides continued to jockey for power. Armed clashes occurred, the most serious being in January 1941. Political stalemate resulted.

Mao intensified party discipline to prepare for seizure of power following Soviet entry into the Japanese war and the gradual demoralization of Chiang's regime. In 1947 the Communist "People's Liberation Army" launched full-scale war upon Chiang while the Communist Party sought popular support with a land reform program that distributed to tenants and poor farmers the lands of landlords in areas under its control. On Oct. 1, 1949, the Communists, having been victorious on the mainland, proclaimed the People's Republic of China in which the Communist Party became the dominant political factor, although it organized minor subservient groups, called political parties, to unite intellectuals and small-scale capitalists in support of Communist policies. In 1966 a factional struggle began in anticipation of Mao's death. An Army faction opposed the Communist Party functionaries, claiming approval of the aged Mao. Teen-agers, organized as a "Red Guard," were encouraged to attack the functionaries as insufficiently militant. By 1966 the struggle was intense and the outcome unclear.

**United States.**—Communism emerged in the U.S. only after Russian Communists encouraged left-wing elements to separate from the Socialist Party in 1919 and to imitate Moscow by creating a Communist Party. After subsequent dissension had splintered the party and deportation from the United States had removed some of its noncitizen leaders, Moscow ordered creation in 1921 of an open party to operate legally. Thus emerged the Workers' Party of America, but the Communist Party was continued as a secret group until 1923 when Moscow ordered its complete elimination. Factional intraparty conflict, which became characteristic of the party, continued in the legal party requiring Moscow's intervention to restore party discipline in 1929. A Communist Party of the United States was then re-created as an avowed section of the Communist International.

Dissolution of the Communist International by Moscow in 1943 to curry favour with Western democracies in the joint war against Hitler's Germany required reorganization of its U.S. affiliate. The Communist Party's constitution, in its revised form that had been adopted in 1938, contained no statement of relation to Moscow. The party sought to associate itself in the public mind with American democratic traditions. This trend toward masking the party's revolutionary role and its Moscow orientation was accentuated with passage by the U.S. Congress in 1940 of the Voodoo Act requiring registration of organizations subject to foreign control. To escape the law's provisions the party adopted a new and less militant constitution and went so far as to re-form in 1944 into what was called a "political association," having as its stated aim collaboration within the historic U.S. two-party system for victory in the war.

Defeat of Germany and Japan in 1945 brought an immediate change for the U.S. Communist Party on orders from Moscow. The mask of political association, which had proved effective in recruitment of politically uninformed Americans during the period of wartime collaboration with the U.S.S.R., was put aside. The Communist Party of the United States was re-created, but its constitution sought to avoid anticipated distrust on the part of U.S. patriots by retaining the earlier espousal of democratic traditions. Revelation of the excesses of Stalin's personal dictatorship over the Communist Party of the Soviet Union, following his death in 1953, caused many resignations from the party, as did mounting exposure of party aims by U.S. scholars and public associations and enactment of restrictive legislation. Membership fell to 8,000 according to a 1958 estimate of a congressional committee.

Following revelation of Communist infiltration of the federal bureaucracy and in the heat of hostility against Communist China during the Korean War the McCarran Act was enacted in 1950. It made criminal "knowingly to combine or conspire with others to perform any act which would substantially contribute to the establishment within the United States of totalitarian dictatorship, the direction and control of which was to be vested in any foreign government, foreign organization or foreign individual." Laws of similar intent were enacted in some states. Communists were excluded thereby from the school system as teachers, from foreign travel, and from labour union leadership without disqualification of their unions from the protection of the Taft-Hartley Act. Some state laws denied them the right to run for elective office. By an act of Aug. 24, 1954, the Communist Party was further hampered, and it claimed that it had been "outlawed."

Communist Party senior officials were convicted in 1949 under the Smith Act of 1940, and the U.S. Supreme Court upheld the convictions. The 1940 act made it a criminal offense to advocate overthrow of any government in the United States by force or violence. Subsequent convictions elicited a clarification from the Supreme Court in 1957 that teaching and advocating forcible overthrow of the government were not punishable under the Smith Act so long as such teaching and advocating were divorced from the effort to instigate action. Enforcement of state antisedition laws was nullified by a Supreme Court decision in 1956 declaring a Pennsylvania statute an unlawful assumption of authority in a field preempted by the federal government.

The effect of the 1954 "outlawry" remained unclear as no judicial review of the statute occurred immediately and the Communist Party ceased to run candidates. The Communist Party continued however to hold congresses. The 17th was held in 1959 and elected William Z. Foster as chairman emeritus, Eugene Dennis as national secretary, and Gus Hall as general secretary.

A long legal battle by the U.S. Communist Party against the registration requirements of the Subversive Activities Control Act of 1950 ended in 1961 when the U.S. Supreme Court upheld the act as regulation and not prohibition, but the party continued to resist. In 1964 the Supreme Court declared unconstitutional prohibition of foreign passports to all Communists without consideration of degree of engagement in party affairs. In 1965 the Supreme Court rejected the 1950 act's requirement that individual Communists register as violating the Fifth Amendment.

Emboldened by these legal victories the Communist Party held a congress in 1966 and announced resumption of open activities, publishing a program.

**Moscow Influence.**—Formal evidence of Moscow's influence on Communist parties throughout the world appeared and disappeared over the years. After dissolution of the Communist International in 1943 there was a gap until 1947 when a Communist Information Bureau was established but it was dissolved in 1956. In 1957 a declaration of unity of purpose was signed by most Communist parties in Moscow, and thereafter an international monthly organ called *World Marxist Review* appeared in various languages. This apparent unity dissolved after 1960 under pressure of the Sino-Soviet denunciations (see COMMUNISM: Sino-Soviet Denunciation).

**Program.**—Communist parties in all countries base their pro-

grams upon the general principles set forth by Karl Marx and Friedrich Engels in the *Communist Manifesto*, 1848. In adapting these principles to their various needs, the parties have taken into consideration the special economic and political conditions existing in the countries in which they have been active. Programs changed from time to time as conditions changed, but the ultimate objective remained the same.

The Bolshevik faction of the RSDLP, appearing at the Congress of 1903, prepared a program which was redrafted after the Russian revolution of 1905 to incorporate the experience of the party. It was revised again in 1919, following the practical experience of the party in governing the new state. The 1919 revision remained the program until Joseph Stalin's death in 1953, after which it was replaced by a new one in 1961. The 1919 version analyzed the capitalist system of economy in Marxist terms and heralded the liberation of society from recurring depressions and oppression by social revolution, brought about by the dictatorship of the proletariat and its vanguard, the Communist Party. It set as the aim of the party the realization of the highest type of democracy, and declared this as requiring a continually rising standard of culture, organization, and activity on the part of the masses. It expressed its firm belief that the cornerstone of such progress was the principle of state ownership of the means of production—the land, forests, waters, subsoil, and industry; as well as transportation, banking, and trading instrumentalities.

Equality of all nationalities was demanded and the federative system of organization favoured. Even political separation was regarded as a right, but the party was directed to consider such requests in the light of which class expressed the desire for separation and the level of historical development of the nation. Separation had to be a progressive step to receive party sanction.

Jurisprudence was to represent class interests. Courts were to be simple and accessible to the population, and judges to be elected from the working masses and only by the working masses. In the absence or incompleteness of decrees, judges were to be guided by Socialist conscience. Sentences were to be designed to rehabilitate rather than to punish. The school was to be made an instrument for Communist regeneration of society. It was to transmit to the semiproletarian and nonproletarian sections of the toiling masses the intellectual, organizational, and educational influences of the proletariat in order to educate a generation capable of establishing communism.

Separation of church and state was favoured, together with an ultimate aim of liberation from religious superstition, without offending the religious susceptibilities of believers. An economic base of state ownership of the means of production was demanded. Emphasis was placed upon labour unions as the organizing apparatus of socialized industry, and as a means of establishing a new Socialist discipline. Agriculture was to be organized on a Socialist base through communes, state farms, and assistance to cooperative farming societies. Private trade was to be replaced by distribution through cooperatives. Banking was to be a state monopoly. It was appreciated that money would not be abolished, but its use was to be reduced. A progressive income and property tax was favoured, with ultimate financing of the state by income from the various state monopolies. Housing improvements, protection of labour by progressive labour laws, social insurance, and expansion of public health were also advocated. The 1961 program's principal innovation was to declare ended the phase of proletarian dictatorship. Both Communist Party and Soviet state were heralded as representing the entire people. In foreign policy the 1961 program established the principle of "peaceful coexistence," characterized by continuing ideological struggle with capitalism but shunning measures likely to cause world war.

China's Communist Party's program was frequently modernized in contrast to the Soviet party's long-unchanged program. In its 1956 version the Chinese party demanded application of Marxism-Leninism in a flexible and creative way, developing theory by integrating what it called the universal truths with China's revolutionary practice. Emphasis was placed on industrialization, on modernized agriculture, communications, transport, and national defense, as essential to consolidation of what was called China's

people's democratic dictatorship based upon centralism and with reverence for discipline.

The Communist Party of the United States in its 1966 program declared itself "a revolutionary party whose aim is the fundamental transformation of society." Through application of Marxist-Leninist political theory it seeks to install the working class and its allies in power through exercise of the electoral and legislative process, stimulated by pressures exerted through "strikes, boycotts, demonstrations, sitdowns, sitins and others."

Thereafter it would amend the United States Constitution to abolish private ownership of productive wealth and "employ its powers to suppress any violent attempt by a recalcitrant minority of propertied interests to nullify the popular mandate."

The Yugoslav Communist Party under Tito's leadership incurred Moscow's anger by adopting a program in 1958 deviating from traditional Moscow theories. It denied the absolute necessity of revolution to achieve power for the working class in non-Soviet states; it envisaged working-class assumption of power through democratic processes as capitalism decayed and entered into a phase called "state capitalism." It also rejected as dogmatic Moscow's concepts of the steps necessary to transform society in a state under Communist Party control to a condition of complete communism.

**Rules.**—Membership requirements and party structure were defined for each Communist Party by its constitution or "rules." The Soviet party's rules provided the model. In their revised form of 1952 the party was declared, in continuation of concepts established by Lenin in 1905, to be a unified, militant organization held together by conscious discipline. Any deviation from the program or rules, any violation of discipline, or any organization of factional groupings was cause for expulsion. Freedom of discussion within party organizations was guaranteed, but only to individuals. No prior arrangement with others to support a particular view in meeting was permitted. No strengthening of a resolute minority by organization of a voting bloc was to be permitted by the majority when a matter was introduced for discussion. Attempts to organize such blocs were made, but when discovered and overcome, their organizers were frequently expelled from membership.

Decisions taken by party groups were made binding on all members. No lobbying for reversal and no public speeches in opposition were permitted. An opportunity to criticize had to be awaited when the matter was reopened for discussion. Punishment for violation of discipline ranged from mild admonition through public censure, temporary removal from party or government office, to expulsion. If the act causing expulsion could be identified as criminal under state laws, prosecution by state officials followed. The party assumed no power to order punishment more severe than expulsion. Consequently, Stalin's severest political critics were accused of conspiracy to overthrow the Soviet state to make possible conviction and execution for commission of crime.

Membership was not easy to attain by the 1952 rules. All candidates, except for persons who were members of other political parties before the Revolution, were required to present recommendations from three party members of not less than three years' party standing. Mere social acquaintance was not reason for recommendation. Support of the applicant had to spring from association at the candidate's place of work. Recommendations could not be given lightly since the rules declared that those who recommended applicants were responsible for the good quality of their recommendation. This meant that a supporter might lose his own membership if his candidate proved undesirable for reasons which could have been known prior to his admission to membership. Former members of other political parties before the Revolution were required to provide two recommendations from persons who had been party members before the Revolution and three recommendations from party members of at least ten years' standing. Admission of such a candidate was further restricted since the ratification of the Central Committee of the party was required. All applicants accepted for membership were required to spend one year as candidates before final admission to membership. During the probationary period they were required

to study and perform assignments designed to determine their ability, performance of orders, discipline, and self-sacrificing willingness to place everything in a position secondary to party demands. Applicants for admission to membership were required to be at least 18 years of age. A 1961 revision restated the same principles but instituted the concept of rotation in office for all but top party leaders.

Admission to membership in Communist parties outside the U.S.S.R. was also made difficult. While requirements varied, the principle was recognized that the membership must be composed of devoted persons willing to work vigorously for party objectives and prepared to accept party discipline. In non-Soviet countries rewards were few for members of the Communist Party. For this reason it was not necessary to guard against admission of persons seeking successful public careers to the same extent as in the U.S.S.R. This difference in requirement was reflected in provisions permitting resignation from membership in the parties in China and the United States. In the U.S.S.R. resignation was implied as a possibility but not specifically stated as a right. In practice resignation was discouraged until Stalin's death, but instances occurred thereafter.

**Structure.**—Organization of Communist parties was everywhere hierarchical, there being an organization for the state as a whole, several intermediate bodies at provincial and county levels, and primary organizations at the bottom. Each level sent representatives to the next higher level. No direct election of representatives to the supreme congress was provided. Under the 1952 rules of the party in the U.S.S.R., the party's organizations were created as separate from the organizations of the state, but they paralleled them in most instances. There were organizations for the union as a whole, for each of the republics (except for the Russian Republic where a coordinating bureau existed) and for provinces, counties, and large cities.

The All-Union Congress with its central committee and auditing commission was placed at the top of the Soviet party hierarchy. Convened in regular session every four years or in special session on demand of one-third of the previous congress's membership, it had limited functions compatible with its large unwieldy size and brief sessions. It elected its central committee and auditing commission, approved policy decisions taken by the central committee or proposed by it, and approved amendments presented by the central committee to the party program or rules.

The Central Committee carried the major burden of party work in its meetings, required at intervals of not more than six months. It named members of its three agencies designed to sit in perpetual session. The first, the Politburo (called the Presidium from 1952 to 1966), directed the work of the Central Committee and in fact initiated party policy. The second, the Secretariat, appointed the men to execute policy at lower levels and conducted the paper work of the party. The third, the Commission of Party Control, verified fulfillment of party decisions and instituted disciplinary proceedings against violators.

The Secretariat proved under Stalin to be the seat of power, for it was from here that he launched his campaign after Lenin's death in 1924 to establish himself as dictator by appointing loyal supporters as party functionaries throughout the party. On Stalin's death his heirs resolved publicly to direct the party as a collective leadership functioning through party procedures, but no institutional change was made. By 1957 Khrushchev from the position of first secretary had established dominance, but he ruled with less severity than Stalin, perhaps because the expanding ranks of educated specialists and technicians made necessary by industrialization of the economy created pressures preventing recurrence of Stalin-type purges in which large numbers of the new technical experts had been imprisoned and even executed on allegations of treason or sabotage. In 1964 he was ousted and collective leadership reestablished.

Party organization at intermediate levels corresponded to that at the top. There was a periodic meeting of delegates from below organized as a congress, and also an executive committee and a secretariat. At the bottom membership was grouped in primary party organizations, sometimes known as "cells," stemming from

the instruments designed prior to the Revolution to infiltrate and undermine the tsar's government. These cells were organized in factories, villages, collective farms, educational institutions, and units of the armed forces. A short-lived experiment instituted in 1962 by Khrushchev to increase specialized agricultural and industrial knowledge among Communists at intermediate levels by creating separate agricultural and industrial congresses and executive committees was abandoned in 1965 after his ouster.

The U.S. Communist Party under its 1957 constitution was organized on the basis of "clubs" created in industries, shops, towns, and electoral districts. All clubs in a state comprised the state organization, which created necessary subdivisions in counties, cities, regions, or sections. Thickly populated states might be split into districts, each with state organizational status, while thinly populated states might be grouped in one district with state status. A national organization united all state and district organizations.

Each club elected annually by secret ballot an executive committee and officers, all being subject to removal by majority vote of club members. A state or district organization comprised a convention of delegates chosen by subdivisions to meet every two years and a committee to meet quarterly similarly chosen, but subject to confirmation by the convention. Representation on both bodies was proportional to party membership in the group represented. The convention might add to the committee up to one-third more members at large, thus retaining power over the committee, but the committee might dismiss convention officers by affirmative two-thirds vote. The national organization was similarly composed of a convention and committee but also had a smaller executive committee including officers. Executive committee members were chosen from among those who had been party members for five years.

**Supporting Organizations.**—The youth of the Soviet Union has been influenced by the party through three youth organizations, specializing in young people of three age groups. These organizations were given the names of the All-Union Leninist Communist League of Youth, known as Komsomols, the Pioneers, and the Little Octobrists.

The Komsomols were organized in 1918 with a membership of young people who had banded together in youth organizations during the revolutionary months of 1917. Many had fought in the Red Guard. While only 22,000 members were represented at the organizational meeting, the number grew to 400,000 in 1920, when it began to fall. After the civil war ended there was no further necessity of military activity among the youth, and the Komsomols lost their purpose for existing. In 1922 a new purpose was established. The organization was directed to engage its members in health, sport, education, and publishing activities. It was also directed to aid in mobilizing youth to take part in special industrial projects. The best known of these were the construction of the city of Komsomolsk-on-Amur in the far east and the Moscow subway project. With this new appeal membership rose from a combined total of members and candidates in 1924 of 632,000 to approximately 6,000,000 on the eve of World War II, 18,500,000 in the mid-1950s, and 23,000,000 in 1967. Membership in the Komsomols was opened to young people of both sexes from the ages of 14 to 26.

The Pioneers were designed for children between the ages of 10 and 15. Admission was made easy, for any child could be admitted to candidacy, without regard to his or her social class and without recommendations. Two months were required as a candidate. Members were to be organized in brigades, attached to the local Komsomol cell. One member of this cell was to be the brigade leader. The organization for very young children, called the Little Octobrists, was re-created in 1957 to provide politically directed recreation for children prior to entry into the Pioneers. It had been abolished during wartime disruption of preschool education, and its functions absorbed in part by the Pioneers and preschool teachers. In 1967 it had 15,000,000 members.

**COMMUNITY PROPERTY**, a form of marital-property ownership involving joint proprietorship by the husband and wife without a merger or impairment of their individual property rights. The concept of community of family goods came to the U.S. from Germanic, Spanish and French sources. Wide variations among the states makes any reference to a single community-property system misleading. There are, however, significant contrasts between the community-property concept of dual ownership and the practices of the common law, even when the latter have been greatly altered by legislation. In the noncommunity states, there are only two classes of matrimonial property, the husband's or the wife's. This means that the principal form of family property, e.g., the wages or salary of husband or wife, belong to each separately. In contrast, the community states provide for a third fund of property. Each spouse may own separately property owned before marriage or acquired afterward from sources outside the marriage.

Ownership of community property is separated from its administration. The husband has larger powers of decision in the management and control of the community property. However, there are limits placed on the husband's power of disposition; powers affecting personal property are usually broader than those over real property. The common-law and equity interests of the spouses in each other's property, such as dower (*q.v.*) and curtesy or their statutory substitutes, are incompatible with community-property practices and generally do not exist in the community states. A distinction is carefully preserved between the separate property of each spouse and the family property, i.e., the community property. In a majority of community states, the income or increase from any separate property remains separate. This result is derived from the language of the statutes and represents a fundamental change from the attitude of the civil law, which treated the usufruct, or gains of separate property which were used by the family, as community property even though the ownership of the separate property itself was unchanged. Strong social policy favouring the class of family property exists in the form of a legal presumption which resolves doubts about the character or origins of property in favour of community property. This presumption may be overcome only by a clear showing of the origin or character of property as separate.

The community states have enacted Married Women's Property acts much like those found in the noncommunity states. However, their main significance lies in the removal of procedural disabilities and not, as in the noncommunity states, in the granting of property rights to married women.

The efforts of several noncommunity states before 1948 to adopt community-property laws solely for income-tax purposes revealed the breadth of misunderstanding about the institution. In community states, husband and wife own the family property together. In the noncommunity states, on the other hand, the main sources of the family property, i.e., the husband's wages or salary, are separate property notwithstanding the nature of the obligations discharged out of such income. In the community states, husband and wife own equal interests in each other's wages and salaries, which comprise the family property and out of which family liabilities and claims must be paid first, even though creditors may in some cases have recourse against the separate assets of one or both spouses. Generally, upon the death of either spouse the survivor continues to own his or her equal share of the community property, the other portion of the community property being subject to the testamentary disposition of the deceased spouse.

The average family lives under a community administration of family goods whatever system of law prevails. Thus the family as an economic unit is recognized. A majority of married persons in western civilizations live under formal community-property regimes either statutory or contractual in application. The laws of France, Spain, Switzerland, Quebec, South Africa, Scandinavia, the Low Countries, the Latin-American countries and the U.S.S.R., since 1922, embody community-property principles. In Germany and Sweden, recent developments have been directed toward an intermediate system combining the best features of separation and community practices. A workable legal concept of family property that takes into account the problems of divorce, administration and accounting and the liabilities of the family unit and the individual spouses is still developing.

**COMMUNITY THEATRE:** see THEATRE: 20th Century: United States: Community Theatre.

**COMMUTATIVE LAWS**, in mathematics, are two laws relating to numbers, one with respect to addition and the other with respect to multiplication. The symbolical forms for these laws are, respectively,  $a + b = b + a$  and  $ab = ba$ . Thus, they are equivalent to the statement that a finite sum or product is unaltered by reordering the terms or factors. The laws, however, do not hold everywhere in mathematics. For example, the commutative law does not necessarily hold for conditionally convergent series such as  $1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$  unless no term in the rearrangement is displaced more than a fixed number of places from its original position. Also there are numbers, such as quaternions, for which the commutative law of multiplication is invalid. The vector product obeys the law  $a \times b = -b \times a$  instead of the usual law.

**COMMYNES (COMINES), PHILIPPE DE** (c. 1447–1511), French statesman and chronicler, whose *Mémoires* establish him as one of the greatest historians of the middle ages, was born at the castle of Renescure, in western Flanders, of a noble family. His father, the lord of Comynnes (now Comines), was a knight of the order of the Golden Fleece. The godson of Philip the Good, duke of Burgundy, Philippe de Comynnes was brought up at the Burgundian court and in 1464 became squire to Philip's son, Charles of Charolais (see CHARLES the Bold, duke of Burgundy). He took part in the war of the League of the Public Weal against Louis XI (q.v.) of France in 1465 and accompanied Charles the Bold on his first expedition against Liège (1466–67). When Charles succeeded to the duchy of Burgundy in 1467 he appointed Comynnes his counselor and sent him as ambassador on missions to England, Brittany and Spain. In 1468 he was present at the famous meeting at Péronne when Charles had Louis XI virtually as a prisoner, and it was Comynnes who negotiated an agreement between them. Recognizing Comynnes' abilities as a diplomat, Louis in 1472 persuaded him to desert Charles the Bold and to enter his service as his chamberlain and confidential adviser. As Charles confiscated his property, Louis in compensation bestowed on Comynnes estates taken from the house of La Trémoille (including the principality of Talmond and the viscountship of Thouars) and appointed him seneschal of Poitou. Moreover, through his marriage in 1473 to Hélène de Chambres, Comynnes acquired other large estates, including Argenton (hence his title of sire d'Argenton). He played an active part in the signing of the treaty of Picquigny between Louis XI and Edward IV of England and in the settlement of the Burgundian succession. Louis also sent him as ambassador to Florence and to Savoy.

After Louis' death in 1483 Comynnes was at first one of the counselors of the regent Anne of Beaujeu, but he intrigued against the government with the duc d'Orléans (the future Louis XII of France) and was implicated in the "Mad War" between the two. As a consequence he was imprisoned for several months and sentenced to have a quarter of his property confiscated and to be confined for ten years to his castle of Dreux. Nevertheless, he was restored to favour by Charles VIII at the end of 1489 and was one

of the negotiators of the treaty of Senlis (1493) between Charles and Maximilian of Austria. Charles subsequently sent him as ambassador to Venice at the beginning of his expedition to Italy (1494–95). Although during the first years of Louis XII's reign Comynnes was—contrary to his expectations—not given any position, he later helped to formulate the king's Italian policy and accompanied him on his campaign against Genoa. He died at Argenton on Oct. 18, 1511.

**The Mémoires.**—The first part of the *Mémoires* of Comynnes dealing with Louis XI's reign, was written during 1489–91. The second part, dealing with Charles VIII's Italian expedition, was compiled during 1495–98. Comynnes, who had received little formal education and knew no Latin, was a writer of considerable talent, remarkable for his psychological perceptiveness, his sense of the picturesque and the vividness of his narrative. Despite his resentment against Charles the Bold and his admiration for Louis XI he succeeded in achieving a fair degree of impartiality. His writings are also interesting for their revelation of his political theories: he insists on the reduction of taxes, which, moreover he thought should not be levied before they had been approved by the estates-general; and—as befits a contemporary of Louis XII, who was known as "the father of his people"—he maintains that the state should encourage the development of the country's economy. Finally, regarding history as an accumulation of useful experience, he draws examples from it for the guidance of princes and offers reflections on the destiny of states. In this respect he may be compared with Niccolò Machiavelli.

Editions of the *Mémoires* (first printed 1524, 1528 and 1552) include those by Mlle E. Dupont, 3 vol. (1840–47), by R. Chantelauze (1881), by B. de Mandrot, 2 vol. (1901–03), and by J. Calmette and G. Durville, 3 vol. (1924–25). There is also an edition of Comynnes' *Lettres et négociations* by J. M. B. C. Kervyn de Lettenhove, 3 vol. (1867–74).

**COMNENUS**, the name of a Byzantine family from Paphlagonia whose members occupied the throne of Constantinople for over a century (1081–1185). Its first member to appear in Byzantine history was Manuel Erotikus Comnenus, an able general who served Basil II in the east. His son Isaac I, the leader of the military nobles and the soldiery of Asia Minor, was emperor (1057–59) after the abdication of Michael VI Stratioticus, the feeble representative of the civil aristocracy. Isaac's nephew Alexius I (1081–1118), the founder of the Comnenian dynasty (1081–1185), was succeeded by his son John II (1118–43), his grandson Manuel I (1143–80) and his great-grandson Alexius II (1180–83), with whom the elder line of the family died out. Alexius II's successor, Andronicus I (1183–85), the son of John II's brother Isaac, was the last Comnenian emperor, but the family continued to play an important part in affairs of state and was allied by marriage to other ruling families such as the Angeli and the despots of Epirus. After the Latin conquest of Constantinople in 1204 Andronicus II's grandsons Alexius and David founded with Georgian help the empire of Trebizond (q.v.; Trabzon), which lasted until 1461, when David Comnenus, its last ruler, was deposed and executed by Mohammed II. See also BYZANTINE EMPIRE.

See C. du Cange, *Historia Byzantina* (1680).

**COMO**, a town of the Lombardy region, northern Italy, capital of Como province and an episcopal see, is located 40 km. (25 mi.) N. of Milan. It is built on a slope that rises to 663 ft. at the extreme southwestern end of Lake Como. On all but the lakeside it is surrounded by mountains. Pop. (1961) 85,828 communa-

In the oldest part of the town the streets are narrow and the buildings irregularly close-packed. The city's centre is in the newer part. The modern Piazza Cavour, open to the lake on the north, divides the lakeside promenade into eastern and western sections. The tower of the Porta Vittoria or Porta Torre (about 130 ft.) is in the Roman style. Two of the oldest buildings are the church of S. Carpoforo (6th century), regarded as the first Christian church and standing on the site of a temple to Mercury,

and the basilica of S. Fedele, built in the second half of the 13th century. The church of S. Abbondio, formerly the cathedral, was consecrated by Pope Urban II in 1095.

The cathedral of Sta. Maria Maggiore was rebuilt in the 15th century and is a lovely example of the fusion of Gothic and Renaissance styles. It contains many art treasures including paintings by Bernardino Luini and Gaudenzio Ferrari and 11 tapestries by Fiandra. Near the cathedral is the Broletto (1215), the ancient Palazzo Comunale, a Gothic building of gray, white and pink calcareous stone. Another medieval palace is the Palazzo Rusconi. In the Palazzo Giovinio is the civic museum of archaeology with objects from the lake dwellings of lakes Como and Varese. Printing is an ancient art in Como and it was there that Baldassare di Fossato printed the *Opus statutorum* of Alberico di Rosate in 1477 and the *Vita di S. Giovanni da Capistrano* in 1479. The two Plinys were born at Novum Comum. The physicist Alessandro Volta is buried in the cemetery of Camnago and is commemorated by the Tempio Voltiano built in 1928.

Como is connected with Milan by railway and road. It is on the international Gotthard line (Milan-Lugano). The most important industry is the old-established one of spinning and weaving silk. The National Institute of Silk, with large workshops and laboratories, offers vocational training. The beautiful surroundings and mild climate, which is particularly suited to winter visits, attract a large number of tourists.

**History.**—The ancient Comum had perhaps a Gallic origin. It was conquered in 196 B.C. by the consul M. Claudius Marcellus. Under Julius Caesar it became a Roman colony. It was a diocese from A.D. 379, when St. Ambrose consecrated St. Felix as bishop. In the middle ages, after the struggle with the Lombards and the Franks, it became a free commune. In an attempt to regain territory lost in a war with Milan, Como took sides with the emperor Frederick Barbarossa in his struggle with the cities of the Lombard league. The emperor built the fortress of Baradello there in 1159. After the treaty of Constance, Como made peace with Milan and became a seignior, first under the rule of Filippo Maria Visconti and then of Francesco Sforza. During this period its silk industry and wool trade played an important part in the Milanese economy. Como followed the fortunes of Lombardy and was successively under Spanish, French and Austrian rule. During the Risorgimento it was ruled by a provisional government until the defeat at Novara (1849), after which it fell once more under Austrian domination. It was liberated in 1859 by Garibaldi. In World War II Como was not liberated by the Allies until the last few days of the fighting. (M. T. A. N.)

**COMO, LAKE** (LAGO DI COMO), in Lombardy, north Italy, lies 52 km. (32 mi.) due north of Milan (it is sometimes called Lario, from its ancient name of Lacus Larius). The lake has three branches, all of approximately equal length (about 25 km. or 16 mi.) projecting northward, southwestward to the town of Como (q.v.) and southeastward beyond Lecco (this branch being also known as Lago di Lecco), the promontory of Bellagio marking the bifurcation. It is formed by the Adda, which flows westward along the Valtellina, into the northern branch and out of the south-eastern. The area is 146 sq.km. (56 sq.mi.), the surface lies 650 ft. above sea level and the greatest depth is 1,345 ft. The lake fills a remarkable depression cut through the limestone ranges that enclose it, and the northern arm once doubtless extended as far as Chiavenna, enclosing the area now covered by the lake of Mezzola. The north wind, the *tivano*, blows during the morning and the south, the *brega*, in the afternoon. The lake is associated with Virgil, the two Plinys and Claudian. The shores are bordered by splendid villas; perhaps the most lovely spot on the lake is Bellagio.

Lecco is a manufacturing town which lies toward the southeastern end of Lake Como. Pop. (1957 est.) 44,990 commune. The Ponte Grande, which spans the Adda, was built in 1336–38 by Azzone Visconti but subsequently enlarged. There is a monument to Alessandro Manzoni (1785–1873), author of the novel *I promessi sposi*. The town is also a centre for mountain climbing. Lecco is connected by railway with Colico, Chiavenna and Sondrio northward and Bergamo to the south.

Cadenabbia, at the centre of the western shore of Lake Como,

is with Tremezzo (almost joined to it) a very popular holiday resort. Several of the towns and resorts on the shores of the lake, including Menaggio and Varenna, are connected by steamer services, including car ferries.

**COMODORO RIVADAVIA**, Argentine city located at the Gulf of San Jorge on the Patagonian coast. Pop. (1956 est.) 45,779. Founded in 1901, it is the major Argentine city south of Bahía Blanca and the centre of the national oil industry. The surrounding arid, windy plain supported only sheep prior to the discovery of oil near the port in 1907. A nationalized corporation, Yacimientos Petrolíferos Fiscales, administers the oil wells. In 1944 the city became headquarters of the Comodoro Rivadavia military district which controlled the fields. Oil tankers and a national highway link the city with Buenos Aires, and in 1949 a natural-gas line, 1,050 mi. long, was built to the national capital. A further administrative change in June 1955 made provinces of the remaining Chubut and Santa Cruz national territories and divided the district at latitude 46° S. The city and northern area were included in Chubut province; the remaining area to the cape was incorporated in Santa Cruz province. (Js. R. S.)
